But while the slave trade has unhappily blasted the prospects of the Church Missionary Society in the Susoo country, and on the Bullom shore, it has opened to them a wide and important field of usefulness in the colony of Sierra Leone. After the abolition of this iniquitous traffic, multitudes of negroes, captured in smuggling vessels, were brought to Freetown, and, as they were in a most wretched forlorn condition, they were settled in towns in different parts of the colony, and were supplied with food and clothing at the expense of government, until they were able to maintain themselves. In the principal of these towns the Church Society established missionaries and schoolmasters, who are proceeding in their labours with every prospect of success. In January 1819, the number of adults and children attending the schools in Sierra Leone was no fewer than 2104.

In 1721, Mr. Hans Egede, a Norwegian clergyman, proceeded to Greenland, with the view of attempting the conversion of the inhabitants to the Christian faith. There, amidst numberless difficulties, and hardships, and dangers, he laboured with unwearied patience and perseverance, but with little appearance of success. Though the Greenlanders often listened to him with wonderful attention, and approved of all he said, it was evident they understood little of his instructions. It is worthy of notice, however, that the immortality of man was a favourite doctrine with them. It pleased them to hear that the spirit did not die with the body; that the body itself would be restored to life at the last day; that friends would meet together in another and a better world; and that they would be no more subject to sickness and sorrow. In Greenland, the Danish government afterwards established a number of other colonies, (See Art. GREENLAND,) and in the principal of them supported missionaries. Many of the Greenlanders have now embraced the Christian faith, and its beneficial influence is obvious in promoting civilization among them; there is a marked difference between their manners and customs and those of their pagan countrymen.

In 1733, Christian David, Matthew Stach, and Christian Stach, three of the Moravian Brethren, proceeded on a mission to this cold inhospitable country. "There was no need," says one of them, "of much time or expense for our equipment. The congregation consisted chiefly of poor exiles, who had not much to give us, and we ourselves had nothing but the clothes on our backs." No description can equal the difficulties, and dangers, and hardships which the Brethren had to encounter, especially during the first years of their residence in that dreary region. By the Greenlanders they were treated with all the caprice common to savages. Sometimes they appeared very friendly to them; at other times they behaved with the greatest rudeness. If the missionaries stopped with them more than one night, they employed every kind of art to entice them to their wanton dissolute practices; and when they failed in this, they endeavoured to weary and provoke them, by mocking and mimicking their reading, singing, and praying, or by accompanying these sacred exercises with their hideous howling, or the beat of their drums. All this, and much more, the Brethren bore with patience, meekness, and serenity; but the savages, instead of being softened by their gentle behaviour, were only encouraged to abuse them the more. They pelted them with stones, climbed on their shoulders, seized their goods, and shattered them to pieces: they even attempted to spoil their boat, or to drive it out to sea, which would have deprived them of their principal means of subsistence. Cheerless, however, as were the prospects of the Brethren for several years, they at length beheld their labours crowned with remarkable success.

> "Fired with a zeal peculiar, they defy
> The rage and rigour of a polar sky;
> And plant successfully sweet Sharon's rose
> On icy plains, amid eternal snows." COWPER.

In January, 1816, the number of baptized Greenlanders connected with the three settlements which the Brethren have established in Greenland, was as follows:

Begun		
1733,	New Herrnhuth,	359
1758,	Lichtenfels,	306
1774,	Lichtenau,	487
	Total	1152

To some these numbers may appear inconsiderable, but let it be remembered they constitute a large proportion of the Greenland nation. The population of this unhospitable country is said not to exceed six or seven thousand; so that, if this estimate be correct, the Christian converts under the care of the Brethren form about one-sixth of the whole inhabitants of the country. Such indeed has been their success, that in the neighbourhood of New Herrnhuth and Lichtenfels, Greenland has for many years past assumed the aspect of a Christian country. A century ago, not a Christian was to be found in the whole of that unhospitable country; now there are no pagans in the neighbourhood of these two settlements, except occasional visitors. A few years ago only two of the converts at Lichtenfels had relapsed into paganism; and at New Herrnhuth, the number was nearly the same. This certainly is a very extraordinary fact, and is a striking proof of the strictness of the Brethren in the admission of persons to baptism, and of the care with which they afterwards watch over them.

In 1771, the Brethren succeeded in establishing a mission on the unhospitable shores of Labrador, after repeated attempts for this purpose had failed. From their first arrival in the country, the missionaries were treated by the Esquimaux in the most friendly manner, and in a short time the most perfect confidence was established between them. No European would formerly have ventured himself alone with these savages, or have spent a night with them, on any consideration whatever; but the brethren travelled over the ice to them, visited them in their winter-houses, and slept among them many nights successively. When they endeavoured to instruct them in the principles of Christianity, the savages often expressed their astonishment at the things which were told them; at other times they would not listen to any thing about religion. They seemed to have some idea of a Supreme Being, who made the heaven and the earth; yet so feeble was the impression, that there appeared among them no traces of religious worship. To convince them of their sinfulness was no easy task. The liars consoled themselves that they were not thieves; the thieves that they were not murderers; and the murderers that they were not Kablunats, *i. e.* Europeans, to whom it seems they assign the highest place in the scale of criminals.* But though the missionaries for several years met with many difficulties and discouragements, they at length beheld their labours crowned with considerable success. In 1817, the whole number of Esquimaux baptized by them at the different missionary settlements in this country, since the commencement of their labours, was as follows:

Begun	
1771, Nain,	172
1776, Okkak,	244
1782, Hopedale,	185
Total,	601

The schools were attended not only by the children, but by the adults, many of whom made considerable progress in learning. They had family worship both morning and evening in all their houses, and it was extremely pleasing to hear them employed in their own habitations in reading the New Testament, which is now translated into their language, and in singing hymns to the praise of the Redeemer.

After the house of Stuart ascended the throne of England, the tyranny of the government, both in church and state, was so intolerable, that numbers of the people fled from their native land, and sought an asylum in the wilds of America, in the hope of obtaining that liberty of conscience among savages, which was denied them by their own countrymen. In 1646, Mr. John Elliot, one of their ministers, began to preach to the Indians in the neighbourhood of Boston. He afterwards translated the whole Bible into their language, and several other useful books. Besides Mr. Elliot, there were a number of other ministers, who exerted themselves with great energy and zeal in instructing the savages; and their efforts were successful in an eminent degree in promoting Christianity and the arts of civilization among them. In 1687, there were six churches of baptized Indians in New England, and eighteen assemblies of Catechumens professing Christianity. Of the Indians themselves, there were no fewer than twenty-four who were preachers of the gospel, besides four English ministers who preached in the Indian language.

In 1734, Mr. John Serjeant settled as a missionary among a number of Indians on the river Housatunnuk, in the province of Massachusetts. His labours among them appeared at first to be attended with considerable success; but the Dutch traders in the neighbourhood never ceased in their endeavours to corrupt them with rum; and though the Indians passed strong resolutions against drinking, and even kept them for a considerable time, yet some of them unhappily relapsed into that and other vices, even after they seemed to be completely weaned from them. In 1811, the Stockbridge Indians, as they are now called, amounted to 475 persons, none of whom we suppose were professed pagans. Of late years they have made considerable progress in husbandry, and other useful arts.

In 1743, Mr. David Brainerd entered on his labours as a missionary among the Indians. Many were the fatigues, the dangers, and the distresses, which he experienced in the course of his labours among them; and no less singular were the faith, the patience, and the self-denial, which he manifested under trials of this description. His success however amply compensated him for all his toils and sufferings. The impression which his ministrations made upon the Indians was truly extraordinary, yet it was at the same time scriptural and rational. Few men were ever more free from enthusiasm than Mr. Brainerd, and none could be more careful to check it in others. A dry eye was often scarcely to be seen in their assemblies; yet there was no disturbance of the public worship. A deep impression was made on their hearts; but there was no boisterous agitation of their passions. All was powerful and efficacious; yet calm and peaceful. The number whom he baptized was not considerable; but there is reason to believe they were in general sincere converts to the Christian faith.

In 1734, a number of the United Brethren proceeded to North America, with the view of introducing Christianity among some of the Indian tribes. To describe

* To savages, written language must appear a very strange inexplicable thing. Once, when the missionaries read to the Esquimaux a declaration of friendship, by the governor of Newfoundland, they would on no account receive the paper into their hands, from a dread that there was something living in it, which could thus convey to them the thoughts of one who was so far distant, and which might afterwards rise and injure them.

the difficulties, and trials, and persecutions, which they experienced in the prosecution of their disinterested labours, would far exceed the limits of this article. In November, 1755, a party of French Indians arrived in the neighbourhood of the missionary settlement. As the family were one night sitting at supper, they heard an uncommon barking of dogs, upon which one of the brethren went out at the back door to see what was the matter. Hearing the report of a gun, several others ran to open the house-door. Here stood a number of Indians with their pieces pointed to it; and no sooner was it opened, than they instantly fired and killed one of the missionaries. His wife also, and some others, were wounded, but they flew up stairs to the garret with the utmost precipitation, and barricadoed the door with bedsteads. Having pursued them, the savages endeavoured to burst open the door; but being baffled in the attempt, they set the house on fire. Two of the family having got on the flaming roof, leaped down and made their escape. Christian Fabricius, one of the Brethren, was the next who made the attempt, but before he could escape, he was perceived by the savages, and instantly wounded with two balls. He was the only one whom they seized alive; and after dispatching him with their hatchets, they cut off his scalp, and left him dead on the ground. All the others who fled to the garret were burnt to death. Senseman, one of the missionaries who made his escape, had the inexpressible grief to behold his wife perish in this miserable manner. When surrounded by the flames, she was seen standing with folded hands, and in the spirit of a martyr was heard to exclaim, " 'Tis all well, dear Saviour." The whole number who perished in this terrible catastrophe was eleven of the missionary family: five only made their escape. The Brethren, however, were the only sufferers: the Indian congregation happily escaped; but yet they lost the whole of their property, for the savages set fire to the town, and laid waste all their plantations.

During the American war, the missionaries and the Indians under their care were involved in one trouble after another; and toward the close of it, a number of the latter were massacred by the white people, in the most treacherous and cruel manner. The Brethren and their congregation had lately been removed to Sandusky, by Colonel de Peyster, the English governor of Fort Detroit, from the flourishing settlements they had established on the river Muskingum; and, as in consequence of this they were reduced to the greatest straits for want of the necessaries of life, a number of the Christian Indians returned, in order to fetch the corn they had left growing in the fields. While a party of them were in that quarter, a band of Americans came into the neighbourhood, with a design to murder them. After a scene of unparalleled baseness and hypocrisy, they made the Indians prisoners, and told them that they must all die next morning. When the day of execution arrived, the murderers fixed on two houses, one for the men, the other for the women and children, to which they wantonly gave the name of slaughter-houses. These poor innocent creatures, men, women, and children, were bound with ropes, two and two together. They were then led into the slaughter-houses appointed for them. There they were scalped and murdered, in cold blood, by these demons in human form. In this horrid manner perished no fewer than ninety-six persons, among whom were five of the most valuable assistants, and thirty-four children. They behaved, according to the testimony of the murderers themselves, with wonderful patience, and met death with cheerful resignation. The miscreants even acknowledged that they were good Indians, " for," said they, " they sung and prayed to their latest breath." This band of murderers was soon afterwards attacked by a body of English and Indian warriors, and the greater part of them cut in pieces. Thus they met that vengeance from the swords of their enemies, which would probably never have been inflicted on them by the laws of their country: a circumstance in which every heart would exult, were it not for the awful consideration, that persons, whose hands were still reeking with the blood of their murdered victims, were but ill prepared to appear before the tribunal of the Almighty.

By the numerous and heavy trials which it has had to endure, this mission, which was long extremely flourishing, has been greatly checked in its progress. The whole number of Indians baptized by the Brethren, since its commencement, may be estimated, we apprehend, at about 1400; but though they have still three settlements among them, the members of their congregations do not amount to 200.

In 1738, several of the Brethren sailed for Berbice, and settled as missionaries among the Indians. Others afterwards proceeded to Surinam, and established different settlements among those in that colony. Some also went as missionaries among the free negroes; but in consequence of the many difficulties and disasters they met with, they were obliged to relinquish all these undertakings one after another. Among the negro slaves in Paramaribo and the neighbourhood, they were more successful. In 1816, their congregations in this quarter consisted of 817 members.

In Demerara, the Methodist missionaries, and some from the London Missionary Society, have also laboured among the negroes with great success.

In 1732, Leonard Dober and David Nitschman, two of the Moravian Brethren, proceeded to St. Thomas, one of the Danish West India islands. As this was the first mission undertaken by the Brethren, it may not be uninteresting to state the circumstances which gave rise to it, especially as they afford an instance of disinterested benevolence, which perhaps has scarcely a parallel in the annals of history. When Count Zinzendorf was at Copenhagen, attending the coronation of Christian VI. the King of Denmark, a negro, called Anthony, contracted an acquaintance with some of his domestics, and informed them that he had a sister in the island of St. Thomas, who was exceedingly desirous of being instructed in the principles of religion; but as she had neither time nor opportunity for it, she often besought the Great God to send some person to shew her the way to heaven. Anthony having soon after visited Herrnhuth, again declared, in the presence of many of the congregation, the desire of his countrymen, and especially his sister, for Christian instruction; but he added, that the labours of the negroes were so accumulated, that they could have no opportunity of religious improvement, unless their teacher was himself a slave, to instruct them in the midst of their daily avocations. In consequence of this representation, Leonard Dober, and Tobias Leupold, two of the congregation, offered to go to the island of St. Thomas, and to sell themselves as slaves, in case they should find no other way of instructing the negroes. Besides this mission in St. Thomas, the Brethren afterwards established others in St.

Croix, St. Jan, Jamaica, Antigua, Barbadoes, St. Christopher's, and Tobago; but the last has been suspended for some years. In some of these islands, their success has been inconsiderable; but in others, it has been very extensive, as will appear from the following statement of the members of their congregations at the latest period we have been able to ascertain them.

Begun	
1732, St. Thomas	2253
1723, St. Croix	7796
1754, St. Jan	1426
1754. Jamaica, about . .	374
1756, Antigua	7652
1765, Barbadoes, . . .	214
1777, St. Christopher's . .	2240
	21,945

In some of these islands, the success of the Brethren has been so considerable, that the members of their congregations form a large proportion of the whole number of slaves; in St. Thomas and St. Croix, they constitute about one-third, and in St. Jan nearly three-fourths of the negro population. Though the utility of the Brethren's labours are now universally acknowledged, yet we may here mention, that it has been stated on high authority, that, among the planters in the West Indies, a Negro is reckoned doubly valuable if he is a Moravian.

In September, 1786, the Rev. Dr. Coke, accompanied by three other Methodist preachers, destined for Nova Scotia, sailed from England for that country; but the captain was compelled, by stress of weather, to change his course, and to land them on the island of Antigua. Having met with a very favourable reception on that and some other islands which they visited, they resolved, instead of proceeding to the place of their original destination, to attempt the establishment of missions in this quarter of the globe. In the course of a few years, the Methodists accordingly sent missionaries to the principal islands belonging to the crown of Britain; and though, from the great instability which appears among their converts, it is difficult to estimate the extent of their success; yet there can be no doubt that, on the whole, they have been highly useful among the Negroes.

In 1819, the Methodist Societies in the West India islands consisted of the following black and coloured members, exclusive of a few white people.

Begun	
1786, Antigua	3594

Besides the Negroes and people of Colour who are members of the Methodist Societies in the West Indies, there are 43,411 of the same description of persons connected with those in the United States, making a total of 62,736.

In the West India islands, the missionaries of all denominations have experienced the most violent persecution from numbers of the white inhabitants. Though the Methodists have of late years been the principal objects of this opposition, yet the Moravians, peaceful and prudent as were their endeavours to instruct the Negroes, were long opposed with no less violence. Not only lawless individuals, and infuriated mobs, have frequently assaulted the Methodist Missionaries, and interrupted them in their labours, but the legislatures of several of the islands, particularly Jamaica, have passed severe acts against them, restricting them in their operations, and punishing them by fine, imprisonment, banishment, &c. It will perhaps scarcely be credited, yet the fact is unquestionable, that so late as the year 1792, a British House of Assembly (St. Vincent's) passed a law, inflicting the punishment of DEATH on the score of religion. To what an extent the Methodists were placed beyond the protection of law is evident, from the following notable decision of one of the magistrates of Barbadoes, in the case of a most outrageous assault on their chapel by a lawless mob: "The offence," said he, "was committed against Almighty God. It therefore does not belong to me to punish it." But though the Methodists have experienced the most violent hostility from many of the white inhabitants of the West Indies, it would be an act of gross injustice, both to the planters and to the missionaries, were we not to state, that such sentiments and practices were by no means universal; that though multitudes were their enemies, not a few were their friends and supporters.*

* As the Methodist Missionaries in the West Indies have been grievously calumniated, we think it nothing more than an act of justice to them, to introduce in this place an extract from Watson's able "Defence of the Wesleyan Methodist Missions," which will show very clearly that the hostility to them was far from universal. "A great part of the money," says he, "expended by the West India mission, has been raised in the colonies, of which a considerable sum has been contributed by the whites. There is scarcely a chapel of any magnitude in any of the islands, in the erection of which the gentlemen of the islands have not assisted by their subscriptions or otherwise. They have given money; lent money in considerable sums till it could be conveniently repaid; made presents of timber, or furnished it on long credit; and lent their Negro carpenters and masons *gratis*. Subscriptions of ten, twenty, fifty, and one hundred pounds, for such purposes, mark both the rank in life, and the opinions of the contributors. Even in Jamaica, where the dark and dangerous fanaticism of the Methodists has been discovered with more sagacity than in other places, this assistance has been afforded. The clergy, though not in general personally active in Negro instruction, have given proofs that they are not opposed to the efforts made for that purpose, and that they apprehend no danger from them. It has not been an unusual thing for their slaves to be members of the Methodist Societies by their wish or consent. The rector of Kingston gave £10. 13s. 4d. currency towards the chapel in that city; and on another occasion, £20. towards the Morant Bay Chapel. The rector of

In 1796, the London Missionary Society commenced its operations with a mission to the South Sea islands. Nine of the Missionaries settled in Tongataboo; but a civil war having arisen on the island about two years after their arrival, three of them were murdered by one of the contending parties; and the others, discouraged by the difficulties and dangers of their situation, retired soon after to New South Wales. A solitary missionary, who settled on Santa Christina, one of the Marquesas islands, returned to England at a still earlier period. The others took up their residence in Otaheite, and though they were at first most favourably received by the natives, yet they met with so many difficulties and discouragements in the prosecution of their labours, that this mission, of which the highest anticipations had been formed, was for many years considered as a kind of forlorn hope. The missionaries at length left Otaheite, as a civil war was on the point of breaking out on that island; and most of the friends of missions, we believe, hoped that they would never return, as there appeared not the slightest prospect of their being useful among the natives.

In 1811, several of them, however, did return; but, for the present, they took up their residence in Eimeo, as the continuance of peace in Otaheite was somewhat doubtful. Soon after their arrival, Pomare the king, who used formerly to show a strong aversion to religious instruction, publicly renounced idolatry, and made a profession of Christianity. With him this does not appear to have arisen from political motives; but from the firm conviction of his understanding, and the deep impression which divine truth had made on his heart. The example of Pomare, in embracing Christianity, produced, as might be expected, a powerful sensation among his countrymen. Instructions which had lain dormant, and convictions which had been stifled for years, now appeared to revive. Many of the people began to inquire for themselves; the congregations of the missionaries, which had hitherto been extremely small, rapidly increased; and great numbers publicly renounced the religion of their ancestors. Idolatry was at length completely abolished, both in Otaheite and Eimeo. The gods were destroyed, the morais demolished, the Arreoy Society dissolved, human sacrifices, and the murder of infants, abolished. Instead of a multitude of idols, morais, and altars, there were now Christian churches in every district; except here and there a heap of stones, scarce a vestige of the old religion was to be seen. The Sabbath was observed with singular strictness; family worship was established in almost every house, and secret prayer was the practice of almost every individual. There was at the same time a material improvement in the moral conduct of the people; the condition of the female sex was considerably ameliorated; the population of the islands, which had previously been diminishing with prodigious rapidity, promised soon to increase, as, in consequence of the abolition of infanticide and other criminal practices, there was already a visible difference in the number of children. This extraordinary revolution was not even confined to Otaheite and Eimeo; it extended, in a short time, to the neighbouring islands, Tetaroa, Tapua-Manu, Raiatea, Huaheine, Taha, Borabora, and Marua; in all of which idolatry was abolished, and Christianity became the professed religion. Besides instructing the natives in the principles of Christianity, the missionaries taught them to read and write their own language. In this attempt, they formerly met with little encouragement; now, their exertions were crowned with extraordinary success. In the different islands, it was supposed there were upwards of six thousand persons who were able to read more or less perfectly. Pomare even issued orders that school-houses should be erected in every district of Otaheite and Eimeo, and that the best instructed of the natives should be employed in teaching others; so that these islands now possess something like an establishment of parochial schools. The art of printing has been introduced, and the press is now in active operation in these islands. The gospel of Luke, when printed, was sold for three gallons of cocoa-nut-oil per copy; and though the impression consisted of 3000 copies, yet several thousands of the natives were sadly disappointed that no more were to be had. Had there been 10,000 copies, it was supposed the whole might have been sold in ten days. The plan of selling the books they printed was adopted by the missionaries in preference to distributing them gratis, with the view of promoting industry among the natives.

In 1814, the Church Missionary Society formed an establishment on New Zealand, with the view of introducing the arts of civilization and the light of Christianity among the inhabitants. Hitherto the missionary settlers have been able to effect little; yet their prospects, on the whole, are highly encouraging.

Such is a general sketch of the principal missions established by Protestants in different parts of the heathen world. Many others we have been obliged to pass

Morant Bay also gave £10. towards the chapel in that place; and when a collection was made in the chapel at Kingston, a little before the persecuting law of 1807, for the purpose of affording aid to the building of Morant Bay Chapel, many respectable ladies and gentlemen of the city were present, who put into the box, some joes, and others doubloons, making in the whole a collection of £74. In other islands, not merely planters and merchants, but members of colonial assemblies, presidents, chief judges, and governors, have not only subscribed to the erection of chapels, but in some instances have paid regular stipends to the missionaries, as a remuneration for their labours in instructing their slaves, and in many instances have done what was of more essential service, have counteracted the designs of "wicked and unreasonable men," who attempted to stir up persecutions, for which no pretence but intolerance and misinformation could be set up." P. 125.

After stating some of the causes which had occasioned so much opposition to the Methodist Missionaries in the West Indies, Mr. Watson adds, "Other causes, which have produced many instances of individual opposition to the missions, and which in some cases have chiefly promoted acts of legislative oppression, could be adduced; but we do not seek occasion of crimination, though the causes of opposition we allude to would greatly explain and fix its character."—" If it should appear that the real offence given by missionaries is their preaching faithfully against certain reigning vices; that among the number of those 'turned to righteousness,' have been many females who were the objects of illicit attachment and licentious intercourse; that the personal ill-treatment which the preachers of 'righteousness, and temperance, and a judgment to come,' have in many cases experienced, has been the consequence of violent resentments produced by checks put upon vicious indulgence, by the introduction of a stronger principle of morality among the slaves and females of colour; and that restrictive laws gravely proposed to legislatures have been, in many instances which might be given, mainly the work of men who had such injuries to complain of, then the whole controversy would be placed in a light in which that party are not, we are persuaded, disposed to have it viewed. On this subject evidence is not wanting, but the necessity of adducing it shall be created only by the conduct of those, who are most anxious to justify their zeal against missions on very different reasons." P. 141.

unnoticed, as they were attended with no remarkable circumstances, or were productive of no considerable effects. Should the reader wish more particular details of Protestant missions in general, he may consult Brown's *History of the Propagation of Christianity among the Heathen*, 2 vols. 8vo. 1814. Accounts of particular missions he will find in the following works: Mather's *History of New England;* Mayhew's *Indian Converts;* Hopkin's *Memoirs relating to the Housatunnuk Indians;* Brainerd's *Life;* Niecampii *Historia Missionis Evangelicæ in India Orientali;* Meier *Missions-Geschichte oder Auszug der Evangelischen Missions Berichte aus Ostindien von* 1737 *bis* 1767; *Neure Geschichte der Evangelischten Missions Anstalten in Ostindien* 6. (W. B.)

MISSISSIPPI River. This immense stream, forming a river of the first order, deserves particular notice in an elementary work. Under the general term Mississippi, we include not only that river properly so called, but every secondary, or confluent body of water which enters into, or contributes to augment the mass of the main recipient.*

Following this plan, the basin of the Mississippi may be naturally divided into four grand sections; first, advancing from east to west, the valley of Ohio and its tributary waters; that of Mississippi and its branches; that of Missouri and its branches; and that of the lower Mississippi, below the mouth of Missouri. Of these sections in order.

Ohio valley.—This very important region embraces about 200,000 square miles of area, equal to 128,000,000 of United States acres. Its greatest length is from the north-east sources of the Allegany river to the head of Bear creek, a branch of Tennessee river, 750 miles. Its greatest breadth, from the sources of the French Broad, to those of the Wabash river, 500 miles. In point of climate, it extends from N. Lat. 34° to 42° 30′, or through seven and half degrees of latitude, affording a very considerable difference of seasons and temperature.

It has been long the opinion of the author of this article, an opinion formed from the fruits of many years observation, that the Ohio region once formed an immense inclined plane; and that the beds of all the rivers have been formed by abrasion of water. This theory is supported by Mr. A. Bourne, author of a large and valuable map of the state of Ohio. The following is a quotation from a manuscript letter from that gentleman on the subject. "The hills are generally found near the rivers or large creeks, and parallel to them on each side; having between them the alluvial valley, through which the stream meanders, usually near the middle, but sometimes washes the foot of either hill alternately. Perhaps the best idea of the topography of this state, (OHIO, which see,) by conceiving the state to be one vast elevated plain, near the centre of which the streams rise, and in their course wear down a bed or valley, whose depth is in proportion to their size, or the density of the earth over which they flow. So that our hills, with some few exceptions, are nothing more or less than cliffs or banks made by the action of the streams; and although these cliffs or banks, on the rivers and larger creeks, approach the size of mountains, yet their tops are generally level, being the remains of the ancient plain. In the eastern part of the state, some few hills are found in sharp ridges similar to those in the eastern states. The base of the hills is generally composed of limestone, free, or sandstone, slate, and gravel, admixed with mineral coal, ochre, &c." *Bourne.*

The author of this article surveyed, in 1815, Pittsburg and its environs, and found the rocks there, as in every other part of the Ohio valley, perfectly parallel to the horizon, of course, speaking technically, floetz formation. The circumstance most conclusive of the fact, that the hills and valleys of this region were formed by abrasion, is the uniformity of elevation and similar material, of corresponding strata on the opposing banks of the streams; phenomena every where visible, where the nature of the country will admit accurate observation. The coal strata near Pittsburg are in every place found about 340 feet above low water level in the rivers of that vicinity.

Embracing the whole Ohio valley in one perspective, it is found divided into two very unequal portions by that river; leaving 120,000 square miles to the south-east, and 80,000 on the north-west. The Ohio, forming a common recipient for the water of the minor streams of both slopes, flows in a very deep ravine, S. 64° W., 478 geographical, or 548 miles in a direct line from Pittsburg to the junction of this river with the Mississippi. The entire length of Ohio by its meanders, is by actual admeasurement 948 miles.

The peculiar features of this river, and its immediate banks, have led to most of the gross misrepresentations respecting the valley in general. The low water surface of the Monongahela at Brownsville, has been found to amount to 850 feet above high tide in the Chesapeake bay. Estimating the fall in the Monongahela to be 20 feet from the borough of Brownsville to the city of Pittsburgh, would produce 830 feet as the elevation of the latter place above the Atlantic Ocean. The apex of the hills in the vicinity of Pittsburg, are within a small fraction of 460 feet above the low water level of the Monongahela, Allegany, and Ohio rivers. By these elements we have 460 added to 830, or 1290 feet as the extreme elevation of the hills near Pittsburg above the Atlantic tides. We may, therefore, if the correctness of our previous theory is admitted, suppose, that the latter elevation was that of this part of the original plain from which the valley has been formed. This elevation evidently declined towards the now mouth of the Ohio, leaving a descent for the waters.

* Geographical precision on the subject of rivers, is much enhanced by the use of the terms basin and valley. Basin, denotes the entire space drained by any river; whilst the space watered by a secondary or confluent stream is denominated a valley; thus in the article before us, we have used the term basin, for the entire region from which flows the mass of water contributing to form the Mississippi, and the term valley in describing the various sections which compose this enormous basin.

The actual elevation of the present surface of the country adjacent to the great central junction of the Mississippi, with its confluents, is not determined with the same precision with that of Pittsburg: but, from the length of the Mississippi below the mouth of Ohio, a near approximation may be obtained. From the mouth of Ohio to that of the Mississippi, the distance is within a small fraction of 1100 miles, which, at 3½ inches to the mile yields 3850 inches, or 320.8 feet, as the entire depression of the Mississippi river, from the mouth of Ohio to the Gulf of Mexico.

The fall in the Ohio river exceeds that of the Mississippi, and has been estimated at about 5 inches to the mile, consequently, if we multiply 948 miles, the entire length of Ohio, by 5, we have 4740 inches, or 395 feet, as the amount of descent in that stream; and, adding 395 to 320.8 feet, we find 715.8 feet as the declivity of the waters from the confluence of the Monongahela and Allegany rivers at the city of Pittsburg, to the Gulf of Mexico.

A very remarkable difference is perceptible between the different elevations of Pittsburg above the Chesapeake Bay and Gulf of Mexico, amounting to more than 125 feet, in favour of the former sheet of water. This apparent phenomenon is explicable on the simplest laws of hydrostatics. The Gulf stream flows from the Gulf of Mexico towards that part of the Atlantic Ocean adjacent to the Chesapeake Bay, demonstrating that a difference of level must exist between the extremes, sufficiently great to admit a current of considerable velocity. That velocity has never been very accurately determined; but, if we allow only 1½ inch per mile, would yield in 900 miles 112½ feet. That the actual fall from Florida channel to the mouth of the Chesapeake Bay, considerably exceeds 100 feet, there can be no rational doubt, when the necessary geographical phenomena are duly examined.

We may, from the data given, consider the valley of Ohio composed of an inclined plane, chequered by the deep channels of the rivers, hills, and extensive flats, the whole resting upon a base of secondary formation. In many parts of this interesting region, as in the state of Kentucky, the beds of the rivers are vast chasms, rather than valleys, in the true acceptation of the latter term. The two opposing slopes exhibit some very curious contrasts. Though considerably most extensive, the south-eastern slope has no extensive remains of the ancient plane; the north-western slope, on the contrary, contains immense remains of the former plane. The rivers which enter the main recipient from the former, rising in or near the north-western ridge of the Appalachian Mountains, are precipitous from their sources, flowing, as already observed, in very deep channels: whilst those streams which enter from the north-western slope, rise out of a level continuous plain, in many places morass, as in part of the states of Ohio and Indiana. The latter rivers are sluggish towards their sources, gaining velocity in their advance towards the Ohio river.

The secondary rivers of the south-eastern slope, are, the Monongahela, Little Kenhawa, Great Kenhawa, Sandy, Licking, Kentucky, Greene, Cumberland, and Tennessee. Those flowing from the north-western slope, are, the Allegany, Beaver, Muskingum, Hockhocking, Sciota, Miami, and Wabash. Of these streams, the Allegany rises in Pennsylvania, flows into New-York, and winding from north-west to west, and south-west, again enters Pennsylvania, forming the north-western, or rather northern constituent of Ohio. No branch of the Allegany flows from the high table land; the region it waters is in some parts mountainous, and every where hilly; the sources of the Allegany flow, however, from the highest point of the valley of Ohio. Advancing westward from the region watered by the Allegany, the sources of the Beaver exhibit the commencement of the great central plain, which separates the two great basins of the Mississippi and St. Lawrence. This plain stretches westward, and, widening in extent through the states of Ohio, Indiana, and Illinois, reaches the Mississippi river. In its natural state, the valley of Ohio was, in the greatest part of its extent, covered by a dense forest: but the central plain presented a very remarkable exception. As far east as the sources of Muskingum, commenced open savannahs, covered with grass, and devoid of timber. Similar to the plain itself, those savannahs expanded to the westward, and on the waters of Illinois river opened into immense natural meadows, generally known under the denomination of prairies.*

We have dwelt with more minuteness on this central plain than we would otherwise have done, from a conviction that it affords phenomena highly illustrative of the peculiar structure of that part of North America. It has been shown in this article, that the surface of Ohio, at the city of Pittsburg, was 830 feet above the nearest tide water of the Atlantic Ocean, and 715.8 feet above the surface of the gulf of Mexico. Lake Erie has been found, by actual and careful admeasurement, 565 feet above the tide water of the Hudson at Albany; consequently, the Ohio at Pittsburg is 265 feet above the surface of Lake Erie; the intermediate distance, in a direct line, 105 miles. Therefore, if a channel was open from the Ohio river at Pittsburg to Lake Erie, as deep as the bottom of the river, and sloping towards the lake by gradual descent to its surface, the waters of Allegany and Monongahela would, in place of flowing down Ohio, rush into Lake Erie with the enormous velocity arising from a fall of 265 feet in 105 miles; or upwards of 2½ feet per mile. When these mathematically established facts are contrasted with the circumstance, that the extreme north-western waters of Allegany, those of Lake Chataughque, rise within three miles from Lake Erie, the singular but real construction of the country becomes apparent. Nothing but actual measurement could render credible, that Pittsburg, situated at the confluence of two streams, each of which, following their meanders, have flown above 200 miles; and one of which, (Allegany,) having part of its source so near the very margin of Lake Erie; and yet, that the city of Pittsburg should be elevated 265 feet above the surface of the lake.

But by far the most remarkable feature of the Ohio valley is, that its real slope does not correspond to the courses of its rivers. It is a fact now well known, that loaded boats at high water can pass from Lake Michigan into Illinois river, and vice versa. We have seen that Lake Erie was 565 feet above the level of the Atlantic tides. The elevation of Lake Michigan above Lake Erie cannot, from the shortness and gentle currents of Detroit river, St. Clair river, and the straits of Michilimachinak, exceed 35 feet. We may therefore assume 600 feet as the level of Lake Michigan. This would correspond very nearly with that of the Ohio river, between the

* Prairie is a French noun, literally translated meadow.

mouths of Miami and Kentucky rivers. Illinois river we will see, presents much more the aspect of a canal than that of a river, whilst the central table land we have reviewed, is so elevated, as to produce water-courses, whose descent is rapid, and those flowing into Lake Erie all precipitated over falls before reaching their recipient. During the continuance of spring floods, loaded boats of large tonnage may be navigated from the rapids of Ohio, by that river, the Mississippi and Illinois rivers, and through the Canadian sea to the cataract of Niagara, without meeting a single rapid; whilst the direct line between the extremes of this navigation, would pass over an elevated ridge. When due attention is paid to the real phenomena of the connected basins of Mississippi and St. Lawrence, the true causes of the apparent anomalies we have noticed are developed. It is at once rendered apparent, that the true slope of the Ohio valley is nearly at right angles to the range of the Appalachian mountains, and that its lowest line of depression, is the channels of the Illinois and Mississippi rivers.

Soil, climate, and productions.—The soil of this interesting section of the earth, is by no means so uniform as is generally supposed, though taken as a whole, may be considered fertile. The alluvial bottoms of the streams, great and small, are generally a deep loam, exuberantly productive. This rich vegetable earth, in many places reaches the apex of the highest hills. Those hills present, however, great variety of soil; always clothed with timber, though often precipitous, rocky, and sterile. The extreme south-eastern part, from the sources of Allegany to the most southern part of the valley in the state of Alabama, presents a mountainous or very broken hilly tract of country, upwards of 700 miles in length, with a mean width of about 100. The soil is on this region extremely varied, and as it contains at its extremities nearly the greatest contrast of latitude of the valley of which it forms a part, the vegetable productions, natural and artificial, are here also most varied. Very few timber trees, known on this continent between N. Lat. 34 and 42 degrees, but which are here found. The most prominent and valuable species of which, are ten or twelve species of oak; hemlock, pine, the Liriodendron tulipifera; five or six species of hickory and walnut; three species of maple, one of which, the Acer saccharinum, is amongst the most singular and valuable trees known on this globe; three or four species of ash, with an immense variety of useful trees and shrubs not enumerated. The Flora is also highly varied and elegant. Medicinal plants abound. Spring water is abundant and excellent.

Of naturalized plants, trees, and shrubs, the number and variety preclude a complete specification. Extending through eight degrees of latitude, and presenting considerable difference of level, the climates admit the cultivation of plants whose powers of resisting the inclemencies, or of profiting by the changes of seasons, are very different. The cereal gramina—wheat, rye, oats, barley, and Indian corn or maize, is every where cultivated. Meadow grasses flourish best in an advance to the north. In the southern part, even where extensive settlements have been made, meadows are rare; but towards the northward, form a large part of rural economy. This observation, though in a more limited extent, may be applied to orchards, and even gardens. Where the crops become very valuable, horticulture is every where neglected, as are orchards, except in the vicinity of cities or large towns. In the region before us, below N. Lat. 36° 30′, cotton commences to be cultivated as a valuable crop. Some culture of this vegetable extends north of the assumed limit, but rather for domestic use than as an article of commerce. The quantity and quality of this vegetable is enhanced, soil and exposure being equal, in a very near ratio, with advance to the south. As we will have more occasion to dilate on this vegetable in the sequel of this article, it would be irrelevant to touch farther on the subject in this place.

The orchard trees generally cultivated in the region before us, are the apple, pear, peach, plum, nectarine, &c.

The mineral treasures of this region compose a large share of its most valuable productions. Iron, salt, and mineral coal, are the most valuable and abundant. Iron ore is found in almost every section of this extensive line. The immense masses of mineral coal are very extensive: those near Pittsburg are only the most abundant and best known. It is amongst the most remarkable features in the natural history of the United States, that from Onondago in the state of New-York, to the south-west angle of Virginia, the earth appears in every place, at a certain depth, to afford water saturated with *muriate of soda*, (common salt.) This indispensable mineral is found where, if wanting, it could not be obtained without very great expense. Salt is now made at Onondago in New-York, Conemaugh in Pennsylvania, and on the Kenhawa and other places in Virginia;—all in the same range.

The Ohio river bounds the tract we have reviewed as far southward as the mouth of the Great Sandy. Here the former turns almost at right angles, and pursuing a course something north of west to the mouth of the Great Miami, again inflects about south west by west to its junction with the Mississippi. This wide curve, in conjunction with a part of the Mississippi, bounds the great limestone expanse of Kentucky and West Tennessee. This latter region, though adjoining the former, presents features essentially different. The base of the Kentucky section appears to be in great part flœtz or secondary limestone, the face of the earth becomes more monotonous; the rivers flow in many places in chasms, walled on both banks by precipices of limestone. Fresh water in many places scarce. Minerals rare, if limestone is excepted. In point of climate and vegetable production, no very material difference appears between the contiguous parts of the two sections under review, except that which arises from soil. In point of extent and fertility, the soil of Kentucky and West Tennessee is generally productive, and in a variety of places highly fertile. Vegetables, either indigenous or exotic, are very nearly, on both sections, on a similar line of latitude, and of equal exposure and elevation. From a lower surface, cotton, and other tender vegetables, are cultivated farther north, near the Ohio, than towards the north-western ridges of the Appalachian mountains. The climate of both will be more amply noticed in the sequel of this article.

Respecting the north-western section of the Ohio valley, a few observations will suffice, after what has preceded respecting that of the south-east, and on the review of the whole valley in general. Similar latitudes present in great part similar climatic phenomena and vegetable products. From the peculiar structure of the north-western section already delineated, it must be evident that mineral products are rare; and such is the fact. Iron ore is found, though not abundantly, in the north-west part of

Pennsylvania, and north-east part of Ohio. Mineral coal abounds along the Ohio, and on some other streams, as far down the valley as Cincinnati, and might, it is probable, be obtained in other places, if the earth was perforated to sufficient depth. Indications of muriate of soda, and some trifling fragments of sulphate of lime, (Gypsum,) have been discovered, but neither to any considerable extent. In the far greater part, however, of this section of the Ohio valley, few or no indications of minerals appear. The flatness and peculiar structure of the two-thirds of the states of Ohio, Indiana, and Illinois, preclude the exposure of mineral bodies, if such existed. It has been by the action of water in wearing deep channels in the earth's surface, that mineral bodies have, in most cases, been exposed to human view and use.

In point of soil, climate, and vegetable production, the south-western section of the Ohio valley has been too highly coloured, though favourable in many respects to human residence. The range of country within one hundred miles of the Ohio river being broken into hill and dale, good wholesome water is abundant, but receding to the central table land, is in many places wanting. In most essential circumstances, as respects natural phenomena and human economy, strong analogies exist between the contiguous parts of the two great sections of Ohio valley, whilst their extremes present a total contrast. It would be mere repetition to dilate further, after what has been given on this subject; the foregoing observation was made in order to draw the reader's attention to features so strongly traced, and illustrative of the subject on which we are treating. It has been too generally prevalent with authors, as well as travellers, to respresent the Ohio valley as a monotonous surface, uniform in aspect, climate, and fertility; whilst, in all these respects, perhaps no equal region of the earth presents, in all these points, more marked or more abrupt contrasts, if some very mountainous tracts are excepted.

Valley of the Mississippi Proper.—Before entering upon the physical survey of the particular valley of the Mississippi, above its junction with Missouri, it is necessary to take a view of the entire stream which now designates the whole basin.

In our defective state of information, it is impracticable to determine which is the most remote branch of the Mississippi, nor is it perhaps an object of much consequence. The latitude and longitude of its source are also undefined. Authorities on that subject differ so much, that no great confidence is due to any. It is probable, that like other rivers, no real certainty of the main source or latitude is attainable without extraordinary pains and skill. We may, however, assume N. Lat. 48°, and W. Long. from Washington city 18°, as the source of that great river. Its general course is about south-west 300 miles, to the mouth of the Corbeau, which comes in from the right. Below the Corbeau, the Mississippi assumes a south-eastern course of 200 miles to St. Anthony's Falls, at the foot of which it receives the St. Peter's, a large tributary stream from the north-west. Below the mouth of St. Peter's, the Mississippi continues south-east 80 miles, and in that distance receives from the left the St. Croix, Chippeway, and Black rivers. Between the two former occurs Lake Pepin, a mere dilatation of the river. After receiving Black river, the Mississippi curves more to the south, and 80 miles below the former, receives from the left a large branch, the Ouisconsin. Thence again turning to south-east 100 miles, is joined by Rock river, a stream of considerable size, flowing from north-east to south-west, and rising near Lake Michigan. Below Rock river, the Mississippi turns to a little west of south, 100 miles, to its junction with the Lemoine river, a very considerable tributary stream from the north-west. One hundred and twenty miles, in a south-eastern course, below the Lemoine, the Illinois unites with the Mississippi, and 15 miles lower, the latter and Missouri form their junction. The entire length of the Mississippi above the mouth of Missouri, is by comparative estimates, 995 miles. The country drained by this river is generally rather level than hilly, much of its surface prairie. Except towards its source, no lakes of any considerable consequence are found on any of its confluents. Its water is tolerably limpid, and its current gentle. Though, from accidental circumstances, the Mississippi has gained the pre-eminence in giving name to the general recipient, it is, nevertheless, a mere branch, and by no means the principal one, of Missouri. Below their junction, the united stream flows 198 miles south-east, where it receives an immense accession of water through the channel of Ohio; below which, the congregated mass turns a little west of south, and flows in that direction 316 miles, receives the White river, and 14 miles lower the Arkansaw; both from the right. The Yazoo enters from the left, 187 miles below the mouth of Arkansaw; and 211 miles below the mouth of Yazoo, the Mississippi receives its last tributary stream of consequence, the Red river, from the right. Two miles below Red river, the Atchafalaya flows out to the south. From the mouth of Arkansaw to the efflux of Atchafalaya, the general course of the Mississippi is nearly from north to south. Below the former, the latter assumes a south-east course, which it pursues 347 miles, to its final exit into the Gulf of Mexico. The entire length of the Mississippi, below the mouth of Missouri, is 1273 miles, by the windings of the stream. If one-third is added to its comparative length above Missouri, for its particular meanders, the result will give 1327 miles, which added to 1273, yields 2500 miles, as the entire length of the Mississippi, following the bends.

Like all rivers of great length, the Mississippi is subject to an annual rise and fall. The periods of those floods are tolerably regular, but the quantity and elevation of the water differs continually, and often to many feet in two succeeding seasons. The river commences its swell generally in March, or the beginning of April. The increase of the water, at first rapid, gradually becomes more slow, until the supply beginning to exhaust, the volume commences its fall or decrease, which, at Natchez, is in a long series of years, from the 15th to the 20th of June, and, at New Orleans, in the first week of July. There is, however, in most years, a lesser and earlier flood, which varies in time, much more than that of the spring and summer. In October, November, or December, this lesser flood intervenes generally, in the last days of December, and first of January. This lesser flood seldom rises so high as to overflow the banks, and it has been observed, that when the earlier flood is more than commonly high, that the later flood is in proportion, lower than common. The efflux of Plaquemine, is the common scale in the Delta of the excess and period of both floods; which article see.

The velocity of the current of the Mississippi has been greatly mistaken. Taking the motion of its swells, the only safe criterion, it is found that, below Ohio, the entire mass does not move as much as one mile per hour. The line of upper current moves more rapidly than the mass, but even the former does not move by any means with the rapidity usually supposed. This subject will be more amply explained under the head of *Rivers*, which see.

The depth of water in the Mississippi varies of course with the increase and decrease of its floods, but this difference of elevation is more perceptible above, than in the Delta. At Natchez it is from 30 to 40 feet, at Lafourche about 23 feet, and at New Orleans about 9 feet. There is usually about 12 feet water on the bars of the North-east and South-west Passes. In the South and West Passes 9 feet, and in those of the North and Pass à la Loutre 8 feet. Above the passes, the river deepens to upwards of 100 feet. At New Orleans it is upwards of 120, and at the Lafourche 153 feet at high water. There is no place below the mouth of Ohio, where the channel is ever less than 12 feet in depth.

Valley of the Mississippi proper; above the mouth of Missouri.—In point of area, the valley of the Mississippi proper is not so extensive as that of Ohio, the former only extending over a surface of 180,000 square miles. Its greatest length is from the sources of the Mississippi river to the junction of that stream with the Missouri, 650 miles, and its greatest breadth from the sources of the Ouisconsin to those of Lemoine river, 350 miles.

Before proceeding farther, however, with the descriptive geographical detail, it may not be considered irrelevant, to review one of those great natural features of North America; without attention to which, no correct conception of its peculiar topography can be obtained. This feature is the great natural meadows, known by the name of Prairie. In a state of nature, with but very partial exceptions, a dense forest covered all those parts of the continent of North America contained in the Atlantic slope; the lower part of the basin of St. Lawrence, below the head of Lake Erie, and two-thirds of that basin to its extreme north-western point; north of the St. Lawrence basin to the 55th degree of N. Lat.; four-fifths of the valley of Ohio; the residue of the continent east of the Mississippi river to the Gulf of Mexico; and west of that stream from 50 to 100 miles. This enormous forest, one of the largest on the globe, remains yet nineteen parts in twenty;—the efforts of man having made but partial inroads on either its mass or extent. This great forest is bounded on its western limit by another region of much greater area, but with a very different character. The second may be strictly called the grassy section of the continent of North America, which, from all that is correctly known, stretches from the forest region indefinitely westward, and from the Gulf of Mexico, to the farthest Arctic limits of the continent. The two regions are not divided by a determinate limit. In passing from one to the other, the features respectively are so blended, that the change is in most places imperceptible; though in some instances extremely abrupt.

In general, the prairie region is less hilly, mountainous, or rocky, than that of the forest; but exceptions in both cases are frequent. Plains of great extent exist in the latter, and mountains of no trifling elevation and mass chequer the former section. We are now to approach the survey of regions in which prairie forms no small part of the entire surface, and will in the sequel reach others, where those seas of grass extend over almost the whole superficies.

The extreme northern source of the Mississippi, strange as it may appear, continues unknown. In Melish's map, it is laid down at Turtle lake, 47° 46′ N. Lat., whilst in Schoolcraft's Map, lately published, the sources of that great river are extended to the Lakes Labeish and Turtle, both extending above N. Lat. 49°: a discrepancy between these two authorities of course exists of 1° 14′ of Lat. The nature of the country, indeed, renders precision on this point difficult, without extreme expense of labour and time. We will assume N. Lat. 48° as the source of this great river; its junction with Missouri being at N. Lat. 38° 56′, it flows consequently through nine degrees of latitude, within a trifling fraction. The length of the Mississippi above the mouth of Missouri, is still less accurately known than the position of its source, every authority differing from each other on the former subject. That nearly all estimates of its length are overrated, there are many weighty reasons to believe. Compared with the Ohio, on most maps, no essential difference appears, when the Allegany is added to the latter. The actual length of the Ohio, by its meanders, we have shewn to be 948 miles, that of the Allegany is about 250; the two distances united amount to 1198, say 1200 miles. For a long period, the Ohio itself was estimated at 1188: more correct information corrected the error. On all maps, and from every information we have seen, the sinuosities of the Ohio are at least as great as that of the Mississippi; we may, therefore, without much risk of material error, give 1327 miles as the maximum length of the latter stream.

The confluent rivers of the Mississippi, advancing from its source along its right bank, are, Leech Lake river, Vermillion, Pine river, Riviere de Corbeau, Elk, Sac, and Crow rivers: these enter above the falls of St. Anthony; below that point are, St. Peter's, Upper Jowa, Turkey, Little Maquauquetois, Galena, Great Maquauquetois, Lower Jowa, Lemoine, and a few other streams of little note between the mouth of Lemoine and that of Missouri. From the left the Mississippi receives, advancing from its source, Thomberry river, Round Lake river, Turtle Portage river, Chevreuil, Prairie, Trout, Sandy Lake river, St. Francis, and Rum rivers. These streams enter above the Falls of St. Anthony. Below that point are, St. Croix, Chippeway, Black, Prairie la Crosse, Ouisconsin, Sissinawa, Riviere au Fevre, Rock, Henderson's, and the Illinois. These streams are given, in most part, from the authority of Mr. Schoolcraft, and are also more minutely detailed, from the circumstances that the valley of the Mississippi proper is yet imperfectly known, of great importance in the geography of the United States, and that the source of intelligence is recent and respectable.

Mr. Schoolcraft estimates the elevation of the sources of the Mississippi at 1330 feet above the Atlantic.* From comparison with our own calculations respecting

* Taking the elevation of Lake Erie, as determined by the actual survey of the New York commissioners, for a basis, we find the surface of Lake Superior to be 641 feet above the Atlantic Ocean. From the head of this lake, following up the St Louis river to the Savannah Portage, and from thence across the dividing ground, to the spot where we first strike the waters of the Mississippi, at the head of the west savannah, the aggregate elevation, at 550 feet. The descent of this stream into Sandy Lake, and from thence into the Mississippi river, will reduce this estimate by the sum of 60 feet. From the junction of Sandy Lake river, to the principal source of the Mississippi in Cassina Lake, we attain an elevation of 162 feet, which, superadded to the former estimates, shews the Mississippi river to originate at an elevation of 1330 feet.—*Schoolcraft's Narrative of the Expedition under Governor Cass, page* 261.

the descent of the Ohio, a very remarkable coincidence appears though founded upon totally independent data.

The valley of the Mississppi, though contiguous to that of Ohio, exhibits an aspect essentially different. The sources of the latter we have found issuing from an elevated, mountainous, hilly, and broken country; those of the former, on the contrary, flow from an immense marshy plain, in great part devoid of timber. The humble elevation of the region from which the sources of the Mississippi are drawn, accounts for the adjacent country remaining in its primitive state, and fully corroborates the correctness of the theory assumed respecting the valley of Ohio.

One of the first observations which strikes the mind on a survey of this extensive tract, is, its general monotony. No chains of mountains of note, or even lofty hills rise to vary the perspective. Some elevations there are towards the sources of the largest confluents, and a few solitary hills, dignified, for want of contrast, by the title of mountains. The Mississippi is traversed by several falls, such as those of Pecagama, about midway between Sandy and Winnepec lakes, at N. Lat. 47° 30′; the Little Falls, at N. Lat. 45°; the Big Falls, below the mouth of the Sac river; and those of St. Anthony, at N. Lat. 44°, immediately above the mouth of St. Peter's river. The view of extensive prairies, when first seen, have an awful and imposing effect on the mind, but that impression is soon lost, and a dreary void obtrudes in its place. Many parts of the Mississippi banks are high, broken, and precipitous; but taken as a whole, this great valley presents few objects upon which those can dwell with interest who pass from the rich ever varying scenery of Ohio; particularly that of its banks and south-eastern slope.

Had the head waters of the Mississippi descended from a mountainous, or even a very high table land, similar to that from which flows the Ohio, with a slope of sufficient inclination, the general face of the country, drained by the former river, would have now assumed an aspect similar to that from which flow the head waters of the latter. But in reality, though on a much larger scale, the Mississippi resembles those of the north-west slope of Ohio valley, in the circumstance of flowing from a flat table land, and in gaining ascent and depth of channel in their progress towards their respective recipients. It is a feature peculiar perhaps to the Mississippi, that the country adjacent to its source and that near its final discharge, are in so great a degree similar in their general physiognomy. A difference of latitude of nineteen degrees precludes much resemblance in vegetable or stationary animal production. But according to Mr. Schoolcraft, who visited its sources in the month of July, the migratory water fowl found there at that time of the year are very nearly specifically the same found at its mouth in the months of December, January, February, and March. "It is also deserving of remark," says that writer, "that its sources lie in a region of almost continual winter, while it enters the ocean under the latitude of perpetual verdure."

Climate, Soil, and Production.—Extending through nine degrees of latitude, the change of climate in the valley of the Mississippi proper, is greater than found in any other valley in the basin of which it forms a part, except the more northern parts of that of Missouri. So defective is our information respecting the larger tributaries which enter the Mississippi above Missouri, that little more need be added respecting the Mississippi valley in general. Suffice to say, that in point of soil, vegetable and mineral productions, (lead excepted,) this valley is in every respect inferior to that of Ohio. The ordinary timber in similar latitudes are nearly the same in both valleys; but towards the sources of the Mississippi, pine, spruce, cedar, maple, and white birch are the prevalent timber trees. In fact, the far greater part of the upper, and much of the lower part of the valley, is composed of prairie, low swamp, or lakes. Much good alluvial land, particularly on the Illinois, borders the streams, but in no moderate proportion to what is found in the valley of Ohio.

In the lower part of the Mississippi valley the exotic vegetables cultivated are, in most part, the same found in our middle states generally. The climate being rather more severe in a given latitude in the Mississippi basin than on the southeast side of the Appalachian mountains, some small difference of vegetable location may exist, but not to any very great amount.

Towards the sources of the Mississippi, the wild rice (zizania aquatica) abound in the swamps, and along the low margins of the rivers and lakes, and constitutes no small part of the food of the natives. Perhaps in an advanced state of society, this species of cerealia, which can be cultivated in places unsuitable to any other vegetable, may become the resource of civilized man, and under skilful culture attain a development similar to what has taken place with other grains, such as wheat, rye, oats, barley, and maize. In fine, in the valley of the Mississippi, we find every object denoting our approach to the wide spreading waste on which we are now to enter.

Valley of Missouri, above its junction with the Mississippi.—The Mississippi having been first discovered, has by prescription given name to the whole basin; but the Missouri, above their junction, is a stream which has drained a country of more than six times the extent of the valley of the former. The error is now without remedy; therefore, though of so much greater magnitude, must, in a geographical point of view, be considered a tributary stream to the Mississippi.

Missouri river rises in the Chippewan, or, as they are absurdly called, Rocky Mountains. What is by preeminence called Missouri, is not the main stream, if our maps are even tolerably correct. The Yellow Stone river is longer than its rival above their junction, and receives larger and longer tributary streams. Assuming, however, Jefferson's river as the extreme source of Missouri, the latter will rise at N. Lat. 44° 20′ W. Long. from Washington City 35°. The general course for about 120 miles is north-east, receiving in that distance several tributary streams. It thence turns north 120 miles, and about N. Lat. 46° 20′, is augmented by Dearborne's river from the north-west. It thence curves to the north-east 80 miles, to the entrance of Marias river from the north-west. Below its junction with the Marias river, the Missouri pursues an eastern course 150 miles, and thence a north-eastern course of 150 miles to the mouth of Yellow Stone river. Estimating the distance from its source by either branch, along the stream, the Missouri has flowed, at its junction with Yellow Stone river, more than 1000 miles, and has drained above 150,000 square miles of surface, mostly prairie. Its volume is here, perhaps, as wide and deep as at its junction with the Mississippi. After receiving the Yellow Stone, the Missouri curves first north-east, and thence south-east, 200 miles, to the Mandan villages, at N. Lat. 47° 25′. Between the mouth of Yellow Stone river and the Mandan villages, the volume of Missouri has gained its extreme north bend at N. Lat. 48° 20′, and has, besides many lesser tributaries, received the Little Missouri from the right, flowing from south-west to north-east. Nearly opposite to the mouth of the latter, the Moose river branch of Assiniboin rises within less than one mile from the bank of the Missouri. At the Mandan villages, the Missouri turns directly south, and flows in that course through four degrees and twenty minutes of latitude, or near 300 miles. In this distance it has received a few unimportant tributaries from the left, and from the right the large streams of Cannon Ball, Wetarhoo, Sarwarcarna, Chayenne, Teton, and White rivers. Below the mouth of the latter, the Missouri turns to the south-east, east, and south, 300 miles, to its junction with the La Platte, an immense body of water flowing from the west, and heading with the Arkansaw, Lewis's, and Yellow Stone rivers. In the latter course, the Missouri has also received from the left the Jacques, Great, and Little Sioux rivers. Below its junction with the Platte, the Missouri flows 200 miles south-east to the mouth of the Kanses river, a large tributary flowing from the west, and heading between the Arkansaw and Platte rivers. The Missouri has now gained nearly the 39th degree of north latitude, and turning to a little south of east 250 miles, joins its vast volume to that of the Mississippi, after an entire comparative course of 1870 miles, and particular course of about 3000 miles. Between the mouths of the Kanses and Mississippi rivers, the Osage, a large branch, enters Missouri from the south west. The Osage is a considerable stream, rising in the angle between the Kanses, White, and Arkansaw rivers.

Our geographical knowledge of the various branches of Missouri, is still more limited than respecting the Mississippi. Of the main stream, as high as the Mandan villages, our notices are tolerably ample. Lewis and Clarke, Stoddard, Brackenridge, Bradbury, and others, have enlarged the public stock of information on this interesting topic: but with all that has yet been published, a feeble light has been thrown upon those immense regions.

The greatest length of the basin of Missouri, is from the mouth of that stream to the head of Marias river, 1200 miles; its greatest breadth, from the sources of the Platte to a few miles south-east of the Mandan villages, 700 miles. The outline is too vaguely known to admit precision, as to the area of this vast extent; it must, however, equal, if not exceed 500,000 square milles, equal to 320,000,000 United States' acres.

General features.—Engrasping the whole valley of Missouri in one view, two remarkable features must command pre-eminence; the turbid muddy appearance of the water, and the very great difference in length and volume of the confluent streams from the right bank, when compared with those from the left bank of the main recipient. Whilst from the right, the Missouri receives such vast branches as the Yellow Stone, Chayenne, Quicourre, Platte, Kanses, and Osage; from the left, all the branches are of minor importance. This characteristic continues to distinguish the valley of the lower Mississippi below the mouth of Ohio; where, to the vast volumes of the White, Arkansaw, and Red rivers, are opposed the very inferior streams, the Yazoo, Big Black, and Homochitto.

It would appear that the Mississippi basin is divided into two immense inclined planes, falling from the two opposing chains of mountains, that of the Chippewan, and the Appalachian; and that the two planes are in a very near ratio to the respective magnitude and elevation of the chains from which they decline. The line of contact between those planes is formed by the Illinois. and thence by the Mississippi, below the mouth of the former; and if we extend our views beyond the Mississippi basin, Lake Michigan is evidently the continuation of this line of depression to the north; whilst to the south-east, the rivers entering the gulf of Mexico, as far as the Appalachicola inclusive, belong to the Appalachian plane; and to the south-west, all streams flowing into the gulf of Mexico, as far the Rio Grande del Norte inclusive, appertain to the plane of the Chippewan.

But to return to our particular subject, that of the Missouri valley. It would be useless to give a list of the smaller rivers of this tract, the names of which are hardly known. A general outline is all that ought to be attempted. The Missouri valley is bounded on the west by the enormous chain of the Chippewan or Rocky mountains, from which flow the sources of the Missouri and most of its largest branches. The exact elevation of the Chippewan, or indeed any of its peaks within the domain of the United States, have never been determined, and the result made public. The general table land upon which those ridges rest must from the great length of the Missouri exceed 3000 feet; perhaps about 5000 feet would be a safe estimate for the gneral elevation of the whole chain, particular peaks excepted.

The Chippewan partakes with the adjacent country the character of nakedness, timber being rare and of stunted growth. Like the Appalachian, and most other American mountains, the Chippewan is formed in collateral ridges, with deep intervening valleys. The rivers rise in these valleys and pierce the ridges in their course. The sources of Missouri extend along the chain through near eight degrees of latitude, or upwards of 500 miles. In this region the main stream and most of its tributaries flow to north-east. The sources of Big Horn, a branch of the Yellow Stone river, rise at N. Lat. 41° 30′, whilst Marias river has its most northern source above N. lat. 48° 30′. Some of the northern confluents of Missouri probably lie as far as N. lat. 50.

Missouri leaves the Chippewan by falling over continued ledges of rocks, in a distance of 18 miles; after which, this overwhelming mass of water is augmented every few miles by large tributary waters, without falls or even shoals to its mouth. The channel is deep, and bounded by enormous precipices of rock. The immediate margin of the streams only excepted, this almost interminable expanse is priarie, devoid of timber; and except the deserts of Arabia, no part of the earth presents an equal surface, less inviting to civilized man, than the far greater part of the valley of Missouri. Its asperities become more apparentas information respecting its real features expand. The general character of this extensive valley may be completed in few words; that, with some very partial exceptions, it is a wide and arid waste in summer, and over which in winter, the piercing winds of the north sweep without impediment, and on which a dense civilized population can never exist.

Climate, Soil, and Productions.—In so wide an extent a very great diversity of climate must necessarily exist. From the considerable elevation of some parts, northern position of others, and the open exposure of nearly the whole extent, the winters are extremely severe. The whole of the valley, a small part of the south-eastern extremity excepted, has an aspect and climate with a striking resemblance to the steppes of central Asia; and, like those steppes, must for ever be thinly peopled.

With the exception of the alluvial banks of the streams, the soil is, as far as correct information has been obtained, dry and sterile, which, added to the want of timber, and in many places of great extent, water, settlement of an agricultural people is rendered not only difficult but impossible.

The state of Missouri, embracing about 63,000 square miles, it is probable, if the advantages of climate are superadded to soil, possesses one fourth part of the productive surface of this entire valley.

Of the indigenous vegetables of the Missouri valley little can be said. Mr. Bradbury was the only naturalist of sufficient skill to investigate the subject of its botany, who ever reached the interior of the valley, as far as the Mandan villages, and his opportunities of observation were so limited as to preclude extensive research.

Of the timber trees and exotic plants, we will have an opportunity to speak under the article, State of Missouri, (which see.)

It is probable that the mineral treasures of this extensive valley may in some measure compensate for its many other disadvantages. Of the quantity of iron ore and mineral coal laid open to the day along the banks of Missouri, Mr. Bradbury expresses himself in raptures. So small a part has been examined, and that so hastily, even by Mr. Bradbury himself, that no conclusive deductions can be made on any branch of the natural history of the valley of Missouri, at present.

Valley of the Mississippi, below the mouth of the Missouri.—We now approach what may be strictly designated as the tropical regions of the United States, though the entire surface of the section under review is not included under that government. The common recipient, the Mississippi, has been noticed under the head of that river in general; we may therefore observe, that the section under review extends in its greatest length from the mouth of the Mississippi to the sources of the Arkansaw, 1400 miles: the greatest width of the valley is, from the junction of the Mississippi and Missouri to the mouth of the Atchafalaya, 600 miles. The area of no section of the Mississippi basin can be determined with more difficulty than that under review. The sources and length of the two most considerable confluents remain uncertain to a very serious extent. In this article we have assumed 330,000 square miles, equal to 211,200,000 acres.

In respect to climate, the lower valley of the Mississippi extends from N. Lat. 29°, that of the mouth of the Mississippi, to N. Lat. 42°, the sources of Arkansaw river, or through 13 degrees of latitude, with a difference of elevation from the level of the Gulf of Mexico to at least 5000 feet. These extremes, when due allowance is made for difference of elevation, amount to 28 degrees of latitude.

The principal confluents of this valley, which enter the main recipient from the right, are, commencing below the mouth of Missouri, Merrimack, St. Francis, White, Arkansaw, and Red river; those from the left are, commencing below the mouth of Ohio, Kaskampa, Redfoot, Obian, Chickisaw, Forked Deer, Yazoo, Big Black, Homochitto, and Buffalo rivers.

Features.—The lower valley of the Mississippi is the most diversified section of the United States. Every variety of landscape, every trait of natural physiognomy, and an exhaustless source of metallic and vegetable production, is here found. This expanse is limited on the east by a dense forest, and on the west by the lofty but naked spines of the Chippewan mountains.

After receding about 100 miles from the banks of the Mississippi to the west, and in many places a less distance, prairies commence, which, gradually encroaching on the forests, finally spread one wide waste of grass, as on the higher branches of the general basin. The open plains of Arkansaw and Red rivers, are merely a continuation of those of the valley of Missouri, and with similar features. Those immeasurable plains of grass seem destined to be, in all future, as they have been in all former ages, the empire of ruminant animals, such as the buffaloe, deer, wild goat, or antelope, and wild sheep. Following this apparent law of nature, if those prairies should ever become the residence of civilized inhabitants—those inhabitants must be herdsmen, and not cultivators of the earth. As far as settlements have been made on one side of this grassy desert by the Spanish Americans, and on the other by the people of the United States, in western Louisiana and elsewhere, effects have followed natural causes, and the traveller finds a rude habitation on the banks of a brook or river, with a small field or two, in which a little maize and sweet potatoes are cultivated; and from thence the eye ranges over a shoreless sea of grass, on which cattle and horses are seen grazing in all directions. This is not the fiction of a sportive imagination; it is a reality which the eye that directs the pen that records the fact hath seen innumerable times. And it is here noted as illustrative of how much man is influenced in his modes of existence, his manners, and political condition, by the soil, climate, and other natural phenomena around him; and to the operations of which, as he cannot control, must submit. And such is the flexibility of human nature, that what was necessity becomes by habit pleasure, and the mounted herdsmen of New Mexico, Texas, Louisiana, and Arkansaw, would not change condition with any other people on earth. Free as the plains on which they rove are wide, these horsemen know no luxury beyond their herds, sigh for no distinction but that of managing their steeds with most adroitness.

Such is the germ of a people, which, in the short lapse of two centuries, will inhabit a surface more than equal to two-thirds of all Europe. The mind cannot detach itself from this truly interesting subject without reflecting, that, to the physical similitude between the deserts of Arabia and the steppes of central Asia, with the interminable plains of interior North America, a strong moral resemblance does, and ever must continue to exist between the respective inhabitants of those distant regions.

To the many other features in common between the prairies of Red and Arkansaw rivers, and the steppes of central Asia, is the prevalence of muriate of soda, (common salt,) which, as has been observed, renders the water of those rivers brackish.

When we turn our eye to the entire surface of the valley under review, we find it divided into two very unequal portions. The grand recipient, the Mississippi, is seen rolling almost at one extremity; a narrow strip of land, with rivers of very small comparative magnitude, skirt its left bank. This confined border of about 500 miles in length, by a mean width of 50 miles, amounting to 25,000 square miles, is opposed by an extent of

305,000 square miles, watered by the great volumes of White, Arkansaw, and Red rivers. Consequently the valley is divided into two sections, the proportions of which exceed 16 to 1.

Next to the Mississippi itself, the Arkansaw river would appear the most prominent object on this almost interminable landscape. When the Missouri is assumed as the principal stream, the Arkansaw, in point of length, ranks as its second confluent, being longer than either the Plate, Mississippi proper, or Ohio, which follow in order. The sources of the Arkansaw remain unknown to any precision, but are generally supposed to extend to N. lat. 42°, and W. lon. from Washington city 34°; the position of its mouth has long been sufficiently well known; it enters the Mississippi at N. lat. 33° 56′, and W. lon. from Washington city 14° 10′. This stream, therefore, winds through upwards of 8 degrees of latitude and 20 degrees of longitude. Its length, by comparative course, is about 1400 miles, but, by its meanders, must exceed 2000 miles.

The geography of the Arkansaw has now become an object of the first importance, as its channel forms, from the 100th degree of longitude west of London, to its source, if those sources are south of N. Lat. 42°, part of the limit between the United States and the Spanish dominions in America.

From the discoveries recently made by Captain Long, the magnitude of the Arkansaw has been hitherto underrated. A large body of water hitherto made to enter Red river, is now found to flow into Arkansaw by the Canadian Fork. The Arkansaw is more impeded by falls and cataracts, than any river of the great inclined plane we have noticed. Issuing from an elevated and mountainous region, the bed of this stream is unnavigable with large boats, except about 600 miles above its mouth. From thence it flows in a deep rapid channel, of about six hundred yards wide, to its junction with the Mississippi. The particular tributary streams of the Arkansaw remain in great part imperfctly known. This river now gives name to a territory of the United States, and in the lapse of a few years, will no doubt designate a state of the confederacy, similar to the Illinois, Missouri, ahd Mississippi.

Next in magnitude of volume, and length of course to Arkansaw, is Red river. Like its rival, Red river flows from that spine of mountains, which, ranging from Mexico northward, assumes local appellations in different places; in Mexico this chain retains the native Aztec name of Anahuac; near the sources of Red and Arkansaw rivers, it is known as the Mountains of New Mexico; and farther north as the Rocky Mountains, or the Chippewan.

Great uncertainty reigns over the sources of Red river; but, if the information given by Captain Long be correct, and it is entitled to great credit, those waters which originate from N. Lat. 32° to 35°, and W. Long. from Washington City from 25° to 28°, which in all our maps are represented as flowing into the Gulf of Mexico, by the Colorado and other streams, on the contrary, are the sources of Red river. By comparative courses, this stream is about 1000 miles in length; but following it by its meanders, is probably 1500 miles.

Both the Arkansaw and Red river have their regular periodical inundations, similar to the Mississippi, and enter their recipient at the season of flood respectively, with an immense body of water, which in no small degree contributes to supply that enormous mass of fluid which annually rolls over Louisiana into the gulf of Mexico. Arising from the saline and ochreous earths through which they flow, the waters of these two great rivers are in a considerable degree brackish; that of Red river so much so, that at Natchitoches, and from thence to its entrance into the Mississippi, cannot be used for either drinking or for culinary purposes.

Red river enters the Mississippi at N. Lat. 31° 01′, and W. Long. from Washington City 14° 40′.

The next confluent of the Mississippi, in point of magnitude, which enters from the right bank below the mouth of Ohio, is White river. This latter river, though of greatly inferior length or volume to the two former, is of great importance from the extent of excellent land it drains. White river rises in the angle between Arkansaw and Osage rivers, and has its sources mingled with those of both the latter, also with those of Merrimac and St. Francis. White river, after a comparative course of about 400 miles, falls into the Mississippi, a few miles above the mouth of the Arkansaw.

St. Francis and Merrimack would neither deserve particular notice amid the description of rivers such as we have been surveying, except as flowing from one of the most interesting metallic regions of this globe.

St. Francis rises in the counties of Washington and St. Genevieve, in the state of Missouri, and flowing south by comparative course 250 miles, enters the Mississippi about one hundred miles by water above the White river.

The Merrimack rises in the highlands between the sources of St. Francis and those of the Gasconade, a branch of Missouri, flows east by comparative course one hundred miles, enters the Mississippi eighteen miles below St. Louis.

It is unnecessary in this to notice the soil, climate, or productions of the lower Mississippi valley, as these subjects will come more appropriately under the respective heads of the states of Mississippi and Missouri, which see. A reference is also made to the article Mississippi state, as respects the confluents of the Mississippi river, from its left bank, below the mouth of Ohio.

Summary.

	Square Miles.
Valley of Ohio,	200,000
Do. Mississippi proper,	180.000
Do. Missouri,	500,000
Do. Lower Mississippi,	330 000
Total area of the Mississippi Basin,	1,210,000

We may here remark, that including the basin of Columbia, the Trans-Mississippian Territory of the United States amounts to 1,144,843 square miles, equal to 732,699,520 United States' acres.

To close the survey of the Mississippi Basin, it only remains to examine the general laws by which the annual floods of the Mississippi are regulated and determined. In order to elucidate this subject, it is necessary to combine under one view the entire surface of the basin. This investigation embraces one of the most important questions in physical geography; it is to examine one of the most stupendous operations of nature, performed on a scale commensurate with the magnitude of the effect.

In our review of the valley of Ohio, 320.8 feet was given as the elevation of the waters at the junction of Ohio and Mississippi rivers. From want of correct data as to the real length or general fall of its waters, no satisfactory calculation can be made as to the absolute elevation of the sources of Missouri. We have assumed in this article 3000 feet as the probable height, above the respective oceans, of the sources of the Missouri. In an analysis similar to that on which we are engaged, relative elevation is one of the elements most necessary to a correct result. We may remark in this place, with sincere regret, that during all the time in which our citizens have visited the sources of Missouri, that the elevation of not one peak or pass has been determined and published. We have, however, some facts which enable us, by analogy, to approach an accurate estimate of the height of the sources of the Missouri. From the extreme cold, and from the late continuance of snow at N. Lat. 45° or 46°, we cannot suppose the base of the Chippewan mountains to be in that region less than 2800 or 3000 feet. At the first glance, when it is known the great length of the stream, from its discharge into the gulf of Mexico to its remotest sources, so moderate an elevation of the latter may appear too limited; but 3000 feet would demand very nearly a foot per mile, an enormous descent, much more than double that ordinarily found in rivers. In the foregoing estimate, the absolute height of peaks, or even ridges, are not taken into account.

It has often excited astonishment in those who knew the extent, without duly attending to the structure of the Mississippi basin, that the entire Delta is not annually submerged. We now proceed to investigate the causes of the long continuance, and in common years, the moderate elevation of the Mississippi floods. Recurrence to a good map will render intelligible what is to follow, and render obvious, that the peculiar structure and relative position of the respective valleys which compose this great basin, are the true causes which prolong the duration, and mitigate the height of the annual inundation.

In conducting this review, we may consider the basin subdivided into the four valleys already noticed; that of Ohio, Mississippi Proper, Missouri, and Lower Mississippi. The relative extent of each has been determined, and the principal streams noticed. If we were to turn an attentive eye to a map of those four sections, and unaided by a single fact drawn from actual observation, it would follow from theory, from its more southern position, and from its length extending east and west, that the valley of the Lower Mississippi must first discharge its waters; the Ohio valley would follow; Upper Mississippi would succeed to Ohio; and lastly, would issue the discharge of Missouri, or largest subdivision of the basin: such are indeed the facts.

It would also be evident from inspection, that of every valley taken separately, nature opposes insurmountable obstacles to a simultaneous discharge. Red and Arkansaw rivers flow nearly parallel through fourteen degrees of longitude, and yet in every year the discharge of the former precedes that of the latter nearly a month. Red river is the true North American Nile, though on a smaller scale. That title has been bestowed on the Mississippi with unparalleled absurdity. Except in the single circumstance of each protruding a Delta at their respective mouths, no two rivers could possibly present more contrasted features than does the Mississippi and Nile. In fact, except in one circumstance, very little resemblance exists between the Nile and Red river: the Nile in common years has only one flood, Red river has often two; but the floods of the Nile are discharged by regular rise and as regular depression, which is eminently the case with Red river; a circumstance which, in a very striking manner, distinguishes both from the Mississippi, which rises and falls by pulsation, if such a term is admissible.

Near the north-west angle of Louisiana, a chain of lakes commences on both shores of Red river, which continue to skirt that stream upwards 100 miles. The writer of this article examined these lakes, and found them to be evidently formed in the ancient channels and adjacent low grounds of considerable water-courses, the discharge of which, into Red river, has been gradually impeded by a natural embankment, formed by the sediment brought down by that river. These lakes, as they now exist, are from four or five, to thirty miles in length, and from one quarter to three miles wide, and are filled and emptied alternately, as the floods of Red river rise and fall: they are in fact real reservoirs, which in the rise of Red river receive great part of its surplus water, and as the river depresses discharge that surplus slowly, tending very greatly to mitigate the rapid emission of the Red river flood on the Delta. As far as the writer is informed, this feature is peculiar to Red river, and distinguishes that stream from every other.

Red river, like the Mississippi, has a flood in autumn, but what may be denominated the annual inundation of that river reaches the Delta in February, and continues through March and April.

The efflux of Arkansaw uniformly succeeds that of Red river; but from the greater length of course, extent it drains, and also from the more northerly and mountainous country from which its remote sources are drawn, the volume of the former very greatly exceeds that of the latter; though from different causes, both rivers are alike in yielding their waters by a slow and regular discharge. The great mass of the flood of Arkansaw reaches the Delta in March and April, and is therefore simultaneous with the latter part of that of Red river. White river, in strictness, forms part of the Arkansaw tide, and flows out with the first flux of the latter stream.

We may here observe, that all the rivers of the Mississippi basin, above N. Lat. 37°, are liable to be annually frozen. The Mississippi, at St. Louis, is three years in five passable on the ice with loaded carriages, by the first week in January. The Ohio, in an equal latitude, is not so soon frozen, though the cold is equally intense on the latter, as on the former river. The causes are obvious which produce this apparent anomaly. The waters of the Mississippi, flowing from high latitudes, are cooled almost to the point of congelation, when they arrive at the junction of the Mississsippi and Missouri; whilst those of Ohio, in the latitude of St. Louis, flowing nearly from east to west, demand a longer exposure to frost to become frozen. The gradual melting of the ice and snow above the latitude assumed, that of 37°, is another very controlling cause of the slow emission of the general flood.

The Ohio valley, from its compact form, greater comparative descent, and from the medium climate in which it is situated, emits its waters with more irregularity than any stream in the Mississippi basin. The Ohio tide of flood occurs from November until March, inclusive, though perhaps four years in five, this river yields the principal discharge in the latter month. The floods of this valley are more sudden in their rise, and more impetuous in their discharge, than that of any other section of the Mississippi basin. The main tide of

Ohio reaches the Delta in May. The various streams are, however, so relatively placed, as to render a simultaneous discharge impossible. The effect, therefore, of this river, in producing an augmentation of the floods which inundate the Delta, is much lessened in its operation.

The Mississippi proper is still more disadvantageously situated, to admit a rapid emission of its waters than the Ohio. Flowing nearly in a north and south direction, and through so great a range as nine degrees of latitude, the more southern confluents must be very much exhausted before those towards the source are relieved from fetters of ice. The great body of the Mississippi tide is, however, coeval with that of Ohio.

It is the accumulation of the waters of the three valleys we have surveyed, and those of the Kanses and Osage branches of the Missouri, which produce what is known as the annual Mississippi inundation. This flood, nine years in ten, reaches the highest point of its elevation at Natchez, between the 10th and 20th of June. Few instances occur, in a long succession of years, in which the waters at that city have not commenced their depression by the first week of July. And yet, the heaviest mass afforded by the largest natural section, has not yet reached the Delta.

Powerful as are the natural causes which combine to prolong the discharge of the enormous body of waters contained in the three sections of the Mississippi basin we have examined, none contain such controlling impediments to an aggregated and sudden emission, as does the Missouri valley above the Platte inclusive.

The Yellow Stone and Missouri spread their sources through seven degrees of latitude, and, assuming a general course of south-east, unite their waters above N. Lat. 48°, turn to the east and south-east, and finally assume, at the Mandan Villages, a southern course, after having flown through eleven degrees of longitude. The Platte pursues a general course from west to east, above N. Lat. 40°, and flows through fourteen degrees of longitude. It must be obvious, from what has been shewn in this article, or by inspection of a good map, that the higher branches of Missouri must remain frozen, long after those more southward have commenced their rise, and nearly as late as the period of high tide on the Delta. The mean motion of the entire mass of water, in any of the confluents of the Mississippi, does not much, if any, exceed one mile per hour; therefore, between three and four months are necessary for the passage of water from the extreme sources of the Missouri to the Delta of the Mississippi; consequently, though those waters commence their rise in May, they do not frequently reach the Delta until late in July, or early in August, consequently at a period when the main spring and summer inundation is very greatly abated, and the water retired within the banks of the Mississippi river.

Though the period of flood is well known to the inhabitants of the Delta, and in common years can be calculated within a few days, such is the inequality of the seasons over the whole basin, that no length of experience gives much aid in estimating the probable elevation or quantity. In 1800 and 1801, the waters of the Missisippi at Natchez did not attain the height of the banks.

The Delta commences at the mouth of Red river, or, more correctly, at the efflux of the Atchafalaya. At this place is a gorge, through which the overwhelming mass of surplus water is confined to within three miles; but by the channel of Atchafalaya, a very large quantity flows out to the right from the main stream, never again to return. One hundred and twenty miles lower, flows from the left, the Manchac or Iberville. Those two streams, the Atchafalaya and Iberville, bound the Delta, and below their efflux respectively, no water which flows from the Mississippi ever returns; nor are there any bodies of arable land, except upon the immediate banks of the water-courses; all beyond, is either swamp or morass.

MISSISSIPPI, one of the United States of North America.

Situation and Extent.—Having the Mississippi and Pearl rivers on the west; the 35th degree of N. Lat. or the state of Tennessee, north; the state of Alabama on the east; and the Gulf of Mexico, and N. Lat. 31°, or Louisiana, on the south. The outlines of this state are:

	Miles.
From the mouth of Pearl river along the Gulf of Mexico, to the south-west angle of Alabama, .	80
Along the western boundary of Alabama, to the north-west angle of that state, on the southern boundary of Tennessee, ...	320
Thence west along the southern boundary of Tennessee, to the south-west angle of that state on the left bank of the Mississippi river, . .	90
Thence down that stream to N. Lat. 31°, . .	530
Thence due east along N. Lat. 31°, and the state of Louisiana, to the right bank of Pearl river, .	105
Thence down Pearl river, to the place of beginning,	60
Having an entire outline of	1185

Area 45,760 square miles, equal to 29,286,400 acres. Extreme south, N. Lat. 30° 8′; extreme north, N. Lat. 35°. Length from south to north, 338 miles; medium width, about 135 miles.

The remarkable resemblance in form and geographical position, between the states of Alabama and Mississippi, is obvious on a first glance on their connected maps. In addition to every other point of similitude, both have a prolongation towards the Gulf of Mexico, below N. Lat. 31°, of nearly equal area and extent on that Gulf.

Features, Soil, Climate, and Productions.—Of the rivers of the state of Mississippi, that stream from which the name of the state is derived, claims the first rank.

The Mississippi washes the state from N. Lat. 31° to 35°, a distance, following the stream, of 530 miles. The features of the Mississippi have been so amply noticed under the preceding head, that no farther notice respecting it is necessary in this place.

Next in magnitude and importance amongst the rivers of this state, is the Pearl. This stream rises in the state, about N. Lat. 33°, and flowing in a general course nearly south, flows into the Rigolets between Lakes Borgne and Pontchartrain, at N. Lat. 30° 10′, after an entire comparative course of about 200 miles. From N. Lat. 31° to the mouth of the Pearl, forms part of the boundary between the states of Louisiana and Mississippi.

The Pascagoula rises in the state of Mississippi, about N. Lat. 32° 40′, flows in a southern course to N. Lat. 30° 20′, falls into the Gulf of Mexico after a comparative course of about 150 miles. The main branch of Pascagoula is known by the name of Chickisawhay, as far down as five miles south of N. Lat. 31°, where it forms a junction with the north-west branch, the Leaf river, and from thence to the final discharge takes the name of Pascagoula.

Some streams, but of small note, enter the bay of St. Louis between the Pearl and Pascagoula rivers.

The sources of the Amite, Tickfoha, Tangipao, and Bogue Chito rivers, are in the state of Mississippi.

Flowing into the Mississippi, are the Buffaloe, Homochitto, Big Black, and Yazoo rivers. Of these latter streams, in point of magnitude, the first rank is due to the latter. This river has its source near the southern boundary of Tennessee, interlocking with the head waters of Tombigbee. The Yazoo enters the Mississippi at N. Lat. 32° 30′, after a comparative course of about 200 miles.

Big Black rises about N. Lat. 33°, between the sources of the Pearl and the Yazoo, flows south-west 150 miles, and falls into the Mississippi at the Grand Gulf, N Lat. 32° 5′.

Between the Big Black and Homochitto, the Mississippi river receives the water of Bayou Pierre, Coles creek, and St. Catherine creek; these creeks are comparatively small, but important from their position, and the excellence of the land they drain. The city of Natchez, though so near the bank of the Mississippi, is situated on a branch of St. Catherine creek, which has its discharge 15 miles below.

The Homochitto river rises about 50 miles north-east from Natchez; flows south-west about 100 miles; enters the Mississippi at N. Lat. 31° 12′.

The Buffaloe is rather a creek than a river, not having a course of more than 25 or 30 miles. This stream rises in Amite, and flows west through Wilkinson county, and falls into the Mississippi two miles above Loftus Heights.

The Tennessee river forms a part of the boundary of the state of Mississippi, from the mouth of Bear creek to the Tennessee line, at N. Lat. 35°, about 20 miles, and ought consequently to be classed as one of the rivers of the state.

We have already observed, that the sources of the Tombigbee were in the state of Mississippi. The sources of Tombigbee rise near the Tennessee line, flow to the south-east, and enter the state of Alabama at about N. Lat. 33° 30′.

The state of Mississippi has a very confined and incommodious sea-coast, of 80 miles in extent. In this distance, the Pascagoula is the only inlet by which vessels of the smallest size can enter, and in that only schooners of small draught, at high water, can reach the junction of Chickisawhay and Leaf rivers. The Pearl admits no navigation worth mention; and the bay of St. Louis is a mere indentation of the coast, of no practical use in a commercial point of view.

The Mississippi river is the great harbour and outlet of the state.

The state of Mississippi is naturally divided into four grand divisions of soil. The islands in Lake Borgne, and the Gulf of Mexico; Pine Forest; Mississippi, and other river alluvion; and the Mississippi Bluffs.

Advancing from south to north, first occurs a chain of low sandy islands, lying about six or seven miles from the main shore; their names are, ranging from west to east, the group of the Malheureux (unfortunate) Islands; Mary Anne, Cat, Ship, Dog, Horn, and Petite Bois Islands.

The opposing shore, once a part of West Florida, is a level pine forest to the water edge; constituting the second, and by far most extensive superficies of soil in the state. Receding from the shores of the Gulf inland, the face of the country imperceptibly swells into hills, and though no part of the state rises into elevations that can be designated mountains, much of its surface is extremely broken.

Next in extent to the Pine Forest land, is the range called the Mississippi Bluffs; and lastly, the more confined, but greatly most valuable land, where found above annual overflow river alluvion. Of these three latter divisions of soil in order.

As we have already observed, the Pine Forests reach the waters of the Gulf of Mexico; and, we may add, extend in the intervals between the streams, to the northern extremity of the state. This species of soil, deriving its title from the principal timber it produces, in most places gradually mingles with the river alluvion, or Mississippi Bluffs, and produces an intermediate soil partaking of the qualities of both; and on which oak, ash, hickory, dogwood, sweet gum, and other trees, intermingle with the pine. This mixed soil and timber is known in the country by the name of interval land, and is often found very productive. The pine lands have hitherto been considered extremely sterile; how far future modes of culture, or artificial means, may tend to meliorate this species of soil, remains an undecided problem.

In the northern parts of the state of Mississippi, towards Tennessee, the pine woods are frequently interrupted by a species of prairie, or rather barrens, on which grow shrub oak, and other dwarf bushes; but the soil continues to exhibit the unproductive character of that of the pine woods.

It would not be hazarding much, to estimate the extent of these barren tracts at two-thirds of the entire area of the state.

In all the length of the state of Mississippi, from N. Lat. 31° to 35°, a range of bluffs extend. These bluffs reach, and are washed by the Mississippi in a few places only. Immediately above N. Lat. 31°, rises the highest of these bluffs, known by the name of Loftus Heights, which skirt the river four or five miles. A very large curve of the Mississippi, to the west, leaves an extensive overflown tract along the right bank, as high as Ellis's Cliffs, where, by an eastern curve of the river, the bluffs are again washed by the stream; which is also the case at the city of Natchez. Above the latter place, the bluffs and river do not again come in contact below the Grand Gulf at the mouth of the Big Black river. The bluffs again reach the stream at Walnut Hills, below the mouth of the Yazoo, and at the Chickisaw Bluffs, immediately at the north-west angle of the state.

These bluffs are the mere extension of the comparatively elevated surface of the state of Mississippi over the low grounds of the river of the same name. When the waters are low, it is found that the bluffs are underlaid by a crude concrete of sand and pebbles, held in mass by an oxide of iron; the whole, no doubt, resting on a secondary base.

The elevation of the bluffs vary, but about one hundred feet medium height would not be a serious departure from fact. They are cut into hills by the abrasion of water of the numerous streams which flow from the pine woods in the interior.

What renders these bluffs and hills objects of peculiar intererst, is the quality of the soil, which is in almost all places good, and in many exuberantly fertile. Receding from the bluffs, the pine forests imperceptibly encroach, and in some places, at a more or less distance from the river, say in a direct line from fifteen to twenty miles, closes the productive border.

The foregoing limit is taken in general; many of the water-courses have fertile tracts on their banks, farther into the interior of the state; but the latter description of land belongs more particularly to river alluvion, than to the soil of the bluffs or hills.

The soil of the bluffs and hills is a rich loam, resting on clay; and digging wells has disclosed the fact, that the general substratum to the clay is loose sand.

The whole of this fine border of soil, in a state of nature, is covered with a very dense forest, with an underwood of reed cane, the Arundogigantea, many species of vitis, smilax, and other climbers, and an infinite variety of more humble vegetables.

A mere list of the most prevalent timber trees will serve to demonstrate the fertility of this tract: these are,

Black-oak, Quercus tinctoria.
White-oak, Quercus alba.
Spanish-oak, Quercus falcata.
Black jack-oak, Quercus ferugínea.
Willow-oak, Quercus obtusiloba.
Wild-cherry, Cerasus Virginiana.
Sweet gum, Liquidambar styraciflua.
Poplar, Liriodendron tulipifera.
Large laurel, Magnolia grandiflora.
Beech, Fagus sylvestris.
Fagus pumila, here a tree often forty feet in height, and eight or ten inches diameter.
Black locust, Robinia pseud acacia.
Mulberry, Morus rubra.
Persimon, Diospiros Virginiana.
Honey locust, Gleditsia tricanthos.
Black gum, Nyssa sylvatica.
Cottonwood, Populus angulata.
Linden, Tilia pubescens.
Muscilaginous elm, Ulmus Americana.
Red elm, Ulmus rubra.
Sassafras, Laurus sassafras.
Sycamore, Platanus occidentalis.
Ash, Fraxinus tomentosa.
Black walnut, Juglans nigra.
Bitternut hickory, Juglans amora.
Nutmeg hickory, Juglans myristiecæformis.
Red flowering maple, Acer rubrum.

Of more humble trees and shrubs, and other vegetables, the following are most indicative of fertility of soil.

Papaw, Annonatriloba.
Dogwood, Cornus florida.
Spicewood, Laurus benzoin.
Spanish mulbery, Morus scabra.
Buckeye, Pavia.
Poke, Phytolacca decandra.
Blackberry, Rubus villosus.
Muscadine, Vitis verrucosa.
Reed cane, Arundogigantea.

It would swell this article to too great length, to give a mere list of the most interesting vegetable productions of the fine tract under review; the foregoing are inserted as illustrative of its natural fertility.

When compared with the entire area of the state, the productive tract before us is confined in extent; but when we turn our attention to the exotic vegetables which are, or can be produced within its limits, the intrinsic value of the land is rendered apparent.

Indigo, tobacco, and cotton, have in turn been cultivated as staples, and produced in great abundance: the latter has for more than twenty-five years past superseded the two former, and will, in all human probability, continue the great staple of this part of the United States.

Much speculation has been made upon the quantity of cotton which is, or can be produced per acre, upon the bluff lands. The writer of this article, from some personal experience, will undertake to assume 250 pounds of clean cotton as about an average crop.

To cotton, indigo, and tobacco, may be added, as the exotic plants cultivated in the state of Mississippi, Indian corn, (zea maize,) oats; and, where the inhabitants choose, wheat may be produced; but the culture of that grain is seldom attempted. Most garden plants grow luxuriantly, though good gardens are rare. That species of potatoe, the tuberous rooted solanum, commonly called Irish potatoe, is cultivated, but does not succeed so well, either as to quantity or quality, as the same vegetable does farther northward. The sweet potatoe (convolvulus batatas of Muhlenberg) is produced in the utmost abundance.

Of cultivated fruits, the principal are the apple, peach, and fig, the latter, below N. Lat. 32°, seems to flourish as if natural to the climate. The plum, nectarine, apricot, &c. are cultivated, but not extensively.

Like all the southern states of the United States, meadows cannot be correctly said to exist in the state of Mississippi.

Though the winters are in general mild, the seasons are extremely variable. Frequently frosts occur in sufficient severity to destroy cotton, indigo, tobacco, and other tender plants, as early as the first week in October; whilst perhaps, in the next season, the flowers of the same vegetables will be found blooming in December, and even in January, as was the case in 1805.

No winter, however, passes without frost, and very few without snow, at Natchez. In December, 1800, the thermometer of Fahrenheit fell to 12°, five miles south of Natchez; and often since that period, the cold has been nearly if not altogether as intense. This casual severity prevents, to the utmost southern extremity of the state, the cultivation of either sugar cane or the orange tree; vegetables which are, in fact, confined in the Delta of the Mississippi to a latitude south of most parts of the state of Mississippi.

The bluff lands are followed by the river alluvion, which, though less in quantity, is still more productive, where above annual or casual overflow. From the bluffs confining, and of consequence causing the accumulation of the surplus water of the Mississippi in the spring and summer, there exists less arable soil on the left bank of the Mississippi river, in the state of that name, than on the right bank in Arkansaw territory, and in Louisiana. Some very wealthy settlements on the left bank do, however, exist, with a soil possessing the usual fertility of the Mississippi banks. The arable border varies from half a mile to two hundred yards, and is every where terminated in the rear by overflown grounds, submerged annually from one to ten or twelve feet.

The natural growth on the river arable border is, in general, sweet gum, different species of oak, ash, and hickory, hackberry, sycamore, &c. with an under-growth of reed cane, and below N. Lat. 31° 30′, the palmetto. In the overflown swamps, the principal timber is cypress, tupelo, different species of oak and hickory, maple, sweet gum, and ash. On all other water-courses in the state, more or less alluvion occurs; but in all places is confined in extent, and on the streams in the interior, often merges into the interval land or pine forest.

Taken together, the bluff lands and river alluvion amount to about 5560 square miles, equal to 3,558,400 acres. The bluff lands extend from N. Lat. 31° to 35°, with more or less width, as the rivers intervene.

Confined as the two foregoing tracts of land are, when compared to the area of the state, of which they form a part, they nevertheless form, in the aggregate, the most extensive continuous tract of productive soil in the United States, south of N. Lat. 35°; and when its fertility and local advantages are taken into view, it is hazarding no violence to truth, to estimate this region as one of the most valuable in the United States.

Counties, Towns, Population, and Historical Epocha.— In the state of Mississippi there are 15 counties, as follows, commencing at the south-east angle of the state.

Counties.	Chief Towns.
Jackson,	
Hancock,	
Green,	
Wayne,	
Covington,	
Marion,	Jacksonville.
Pike,	Holmesville.
Lawrence,	Monticello.
Amite,	Liberty.
Franklin,	Franklin.
Wilkinson,	Woodville.
Adams,	NATCHEZ.
Jefferson,	Huntston, or Greenville.
Claiborne,	Gibsonsport.
Warren,	Warrenton.

The returns of the census of 1820 have not yet been received from this state, but the number of inhabitants probably amounts to within a trifling fraction of 60,000; one half of whom are black, or of mixed breed. Of this population, more than half are contained in the five counties bordering on the Mississippi river, Wilkinson, Adams, Jefferson, Claiborne, and Warren. Franklin and Amite, lying east of Adams and Wilkinson, are, after the river counties, best peopled. Lawrence, Pike, and Marion, situated on the waters of Pearl and Bogue Chito, and immediately east of Franklin and Amite, are but thinly peopled; and the five south-eastern counties, Covington, Wayne, Greene, Hancock, and Jackson, have still fewer inhabitants on an equal surface, than are found in Lawrence, Pike, and Marion.

The country near Natchez was settled by the French in 1718, and Fort Rosalie built on the bluff, within the now incorporated limits of that city. The first French colony was massacred by the savages in 1729, and the country remained uninhabited by the whites many years afterwards.

In 1763. Natchez, then considered a part of West Florida, was ceded by Spain to Great Britain, who retained possession until 1781, when that place and all West Florida was conquered by the Spaniards under Governor Bernardo Galvez; and, by the treaty of Paris, West Florida was confirmed to Spain. As the limits of the British and French colonies, and afterwards those between the British and Spanish colonies, had never been fixed, the Spanish authorities held Natchez and the adjacent country as an appendage of Florida until 1798, when the city and country were evacuated by the officers and troops of Spain, and the United States commissioners took full possession. In 1799, the line of demarcation was completed, and the boundary fixed, which now separates the states of Louisiana and Mississippi, between the Mississippi and Pearl rivers.

April 7th, 1798, an act of Congress was passed, authorizing the President of the United States to appoint commissioners to adjust the limits of the territory west of the Chatahoochy river.

May 10th, an act was passed for the organization of a government, and the territory named "The Mississippi Territory."

June 9th, 1808, an act passed, admitting a delegate from the Mississippi Territory in Congress.

June 17th, 1812, the assent of Georgia demanded, for the formation of two states out of the Mississippi Territory. This demand was subsequently acceded to by Georgia.

January 21st, 1815, a petition from the legislature of the Mississippi Territory laid before Congress, praying admission into the Union on the same footing with the original states. A committee of Congrees reported on this petition favourably, December, 1816.

A law was passed in consequence, March 1st, 1817, authorizing the call of a Convention, which was called, and met July, 1817, accepted the terms proposed by Congress, framed a constitution, August 15th, which was accepted by Congress in December following; and the state of Mississippi assumed her station as a member of the United States. Since the period of admission, no event of consequence, in a general view, has taken place in this state.

MISSOURI RIVER. See MISSISSIPPI *Basin*, p. 623.

MISSOURI, one of the United States of North America.

Situation and Extent.—The state of Missouri is bounded, north-east and south-east, by the Mississippi river; south by the territory of Arkansaw; and west and north by the western unappropriated territory of the United States, formerly a part of Louisiana.

The limits of Missouri are:

	Miles.
Beginning on the left bank of the Mississippi river at the mouth of Lemoine river, and thence down the former stream to where it is intersected by N. Lat. 36°, ...	550
Thence due west, along N. Lat. 36°, to the right bank of St. Francis river, ...	50
Thence up St. Francis to a point where that river is intersected by N. Lat. 36° 30′, ...	50
Thence due west, along the territory of Arkansaw, to a point where a meridian line, drawn from the junction of the Missouri and Kanses rivers, will intersect N. Lat. 36° 30′, ...	200
Thence due north to a point, where a line extended due west from the Sac Village, on Lemoine river, will intersect the west boundary, . .	273
Thence due east to the Lemoine river, . .	130
Thence down the Lemoine river to the place of beginning, ...	20
	1273

Area within a trifling fraction of 63,000 square miles, equal to 40,320,000 acres. Mean length from north to south, 280 miles; mean breadth from east to west, 220 miles. Extreme south N. Lat. 36°. Extreme north N. Lat. 40° 26′.

Missouri, in point of extent, is the third state of the United States, and only falls below Virginia and Georgia.

Features.—Though part of this state is hilly, and some of the hills approach in elevation the dignity of mountains, yet, strictly speaking, no mountains, either in detached groups or chains, exist within the limits of the state.

For every object of human affairs, rivers are the most important features of an inland country, and few regions of the earth, of equal extent, can compare with Missouri in the magnitude, number, and navigable facilities of its rivers.

Of these, the first in order is the Mississippi and Missouri, both of which have been already so amply noticed in our description of the Mississippi Basin, that no further account of them is necessary in this place.

The Lemoine river, though for a few miles forming part of the boundary, can scarcely be called a river of Missouri. The Osage, rising in the territory of Arkansaw, and flowing north-east into the Missouri, is the most important confluent of that river in the state of Missouri. The Osage has its mouth near the centre of the state, where the future seat of government is intended to be placed. The Osage is a large navigable stream in all its length in the state, and waters some excellent, and much good land.

Besides the foregoing large stream, the Missouri receives from the right, below the mouth of the Kanses, Blue Water, Gasconade, and some smaller streams; and from the left, Grande, Charlaton, Good-Woman's, Great Manitou, Otter, and Charette rivers. The Merrimack enters the Mississippi 18 miles below St. Louis, but has been noticed under the article Mississippi Basin, as have been White and St. Francis rivers, which closes the list of the streams of the state of Missouri.

The position of Missouri is in a high degree favourable to commerce, population, and wealth. Extending four and a half degrees of latitude, its temperature must vary considerably, if uninfluenced by any other cause than mere geographic extent. This is not, however, the case, as will soon appear.

In conducting this general survey, I have endeavoured, in a particular manner, to delineate those features which influence the meteorological phenomena, and the temperature of the seasons, and also to point out the great outlines of soil. In respect to Missouri, it will be necessary to deviate from the strict observance of the plan pursued in describing the state of Mississippi. Instead, therefore, of dividing the former state into its natural sections, in relation to soil, we will take each of its river districts by itself.

We have seen that the river Mississippi washes Missouri on its north-east and south-east frontier, 550 miles, following the meanders, though, by comparative course, the distance along the Mississippi would not exceed 350 miles. Though the mere banks of the Mississippi preserve a nearly uniform character in all their extent along the front of Missouri, yet, from difference of climate, the vegetable productions are very different at the two extremes. So much has already been said on the features and quality of the alluvial margins of the Mississippi, that it is needless to amplify on the subject.

Ascending the Mississippi from its mouth, no eminence is to be found on its western bank in a distance of upwards of 1000 miles. Twenty-eight miles above the junction of Mississippi and Ohio, occurs the first rocky bluff on the right bank. It is composed of an enormous projecting precipice of limestone, whose real height above the water has never been very satisfactorily determined. This ledge is, no doubt, a continuation of the great limestone formation of the Ohio valley. In Missouri, it is a part of a ridge of hills which continues from this point westward, through the state, and ranges between the waters of Arkansaw and those of Osage and Kanses rivers, perhaps to the Chippewan mountains. This ridge divides Missouri into two very distinct climates. In the south-eastern part of the state, along the Mississippi river, the cotton plant is cultivated, though only for family use; as an object of commerce, it offers no great advantage: but, above the ridge in question, that plant ceases, and a region commences favourable to the production of the cereal gramina.

Near the Mississippi, below the limestone ridge, the banks are in every respect similar to what they have been described in Louisiana. The rear lands, as far as the St. Francis, are analogous to grounds similarly placed, in all the distance from the limestone range to the sea marsh.

The St. Francis rises partly in the hills of the limestone ridge, and in part from the drain of the Mississippi. The north-eastern branch of that stream appears to have been formed from an ancient outlet of the Mississippi, and to have contained a volume of water much larger than passes by its channel at present. The ordinary distance between the two rivers is about 50 miles, flowing nearly parallel from N. Lat. 37° to N. Lat. 34° 30′, where the St. Francis, by a gradual curve towards the lower part of its course, joins the Mississippi. The north-western branch rises near N. Lat. 38°, in a very hilly, broken, rocky, and barren tract of country. There are some good lands, but in no quantity commensurate with the extent drained by this river, whose whole length, by comparative course, is 250 miles, one half in Missouri, and the other in Arkansaw. Extensive settlements have been made on the sources of the St. Francis and its tributaries. According to the very respectable testimony of Mr. Schoolcraft, from personal observation, the country from which the western, or rather north-western source of St. Francis flows, is primitive, composed of granite, gneiss, and other congenerate rocks; amongst which are situated one of the richest iron, and the most abundant lead mine on the globe. The geological notices of Mr. Schoolcraft deserve the utmost attention; because made by a professed mineralogist, and a man who visited the region to collect facts, and not to support any pre-conceived theory. This gentleman has been, it must be acknowledged, much too general on a fact so important as the existence of a primitive region west of the Mississippi, and so near that stream. He has, however, enriched our literature with by far the best account extant of the mineral resources of Missouri, and very correct, though brief notices of its soil and vegetable productions.

Black river, the north fork of White river, rises in the south-western part of Missouri, by a number of branches, of which Strawberry river, Spring river, and Currents river, are the principal. The sources of Black river are in the ridge of hills, or rather mountains, which has been already noticed. The base of the country drained by Black river is calcareous, consequently the soil is very productive. The climate, as to temperature, is in no respect essentially different from that of St. Francis. The former, from superior elevation and more exemption from stagnant water, is no doubt much more salubrious than the latter. Like all calcareous regions, that of Black river affords some very large fountains of water, from one of which Spring river takes its name. The surface watered by Black river is about 8000 square miles. The timber is extremely large and varied. On the streams, cotton wood, different species of hickory, oak, and elm, prevail. The sugar maple is found, but the climate is rather too far south for the profitable extraction of its sap. The Liriodendron tulipifera is also found in this section of country of an enormous growth. Oak is, however, the prevailing tree on the waters of Black river. Like Tennessee, and the southern parts of Kentucky, the vegetation of the southern section of Missouri partakes of the specific variety of the northern and southern extremity of the United States. Cotton is cultivated, but rather for domestic use than as a commercial staple. The cereal gramina produce abundantly: though, on the verge of the prairie country, Black river drains a very dense forest. In fine, that part of Missouri, south of the ridge we have alluded to, and watered by St. Francis, Black, and Mississippi rivers, may be with propriety considered as naturally connected with the Arkansaw basin, though politically included in Missouri. The ridge is generally clothed with pine, the soil sandy, and extremely sterile. It in fact divides the state into two unequal zones, of very different temperature.

The Merrimack rises near the centre of the state; has its source in the dividing ridge, though its course is nearly east along its northern slope. The length of the Merrimack is not above 120 miles, comparative course. Its sources are in a sterile pine forest, and most of its banks partake the character of the soil from which it flows. It is an unimportant stream in either a geographical or agricultural point of view, though, in respect to mineral wealth, one of the most remarkable in the United States.

The mine tract, according to Mr. Schoolcraft, the best authority on the subject, extends in length from the head waters of St. Francis, in a north-west direction, to the Merrimack, a distance of 70 miles, and from the Mississippi, in a south-west direction, to the Fourche à Courtois, a distance of about 45 miles, and covering an area of 3150 square miles. The same author remarks, that it is not in every section of it that lead is to be traced, and he describes the mineral character of the soil, rocks, and other fossil bodies of this tract, as subject to so much variety, as to render indications of ore difficult to reduce to any safe result. The aspect of the country is sterile, hilly, and in many places precipitous. Many highland barrens, level but sterile, chequer the mine district. The soil in general is a reddish coloured, hard, stiff clay, admixed with much siliceous gravel. Nodules of iron-ore and pyrites are frequent. The mineral hills are covered in most places by a stunted growth of oaks, principally the post oak, the quercus obtusiloba of Michaux. A line of pine separates the sources of St. Francis from those of Merrimack, and passes through the mine tract in a direction from north-west to south-east. Though in general the soil of this tract is unproductive, the banks of some of its streams are very favourable exceptions. This fact is elucidated by the forest trees found on this alluvial soil; which are, sycamore, elm, cotton-wood, walnut, maple, buckeye, hackberry, ash, papaw, spicewood, and other trees and shrubbery, indicative of fertile land. Mr. Schoolcraft mentions a fact, of which, from the accompanying remarks, he seems not to have understood the cause. He observes, that around many of the mines, the earth, thrown out and raised from great depths, produces trees and shrubs which are not peculiar to the surface, and instances the cotton-wood, or poplar, and beach-grapes, the vitis riparia, I presume. He states, that he frequently saw those vegetables growing near old diggings, where the earth had been raised thirty or forty feet, and where, previous to those diggings, no such trees or vines existed. It is well known to botanists, that the seeds of many, perhaps most plants, if buried at great depths in the earth, will retain their vegetable organization for countless ages. The indestructibility of the seeds of plants is, indeed, one of the most curious subjects of philosophical reflection and research. Mr. Schoolcraft ascribes the cause of the phenomenon to that opprobrium of science, equivocal generation: a supposition at variance with all the laws of analogy, as applied to organized beings. The fact proves unequivocally, that the country has underwent great changes in its external crust, since the vegetables cited deposited their seeds in the soil, now covered by extraneous and very different bodies.

Here, as in every other place where silica forms a large part of the soil, the spring water is clear, cool, and of course wholesome; and being exempt from the causes that produce disease, stagnant water and decaying vegetables, the mine country is possessed of an atmosphere of the utmost salubrity.

The change of climate between the region watered by Black and St. Francis rivers, and that by Merrimack, is apparent in the vegetables cultivated by the inhabitants of each. On the Merrimack, wheat succeeds extremely well, a fact no where perceptible south of the dividing ridge. Wheat, and indeed all the cerealia, may be, it is true, cultivated even in Louisiana; but below the 38th degree of north latitude, wheat, rye, and barley, evince that they are removed from their congenial climates; and in no part of North America, except some of the table land of the great spine of Analinac, or Chippewan, where elevation compensates advance towards or into the tropics, does the cereal gramina, except maize, attain the full development of their growth. And even maize, in Louisiana, Mississippi, and Alabama, does not by any means attain the rich and abundant produce of that grain, as in the Mississippi basin, above N. Lat. 35°. The same remark applies in a striking manner to the apple. This most valuable of all tree fruits deteriorates about the same latitude with wheat. The apple, west of the Mississippi, first grows to advantage above the mine district. The peach-tree finds its most congenial air about N. Lat. 38°, though it is a fruit possessing in the United States a much wider range than the apple.

The Osage rises about N. Lat. 37°, W. Long. from Washington City 21°, and flows east a little north, having a comparative course of four hundred miles, one-third of which is in Missouri. This river rises in the great western prairies, and, like every stream of that region, exhibits some very productive, and a large proportion of steril land. Its meanders are in the lower part of its course very winding, consequently it contains much alluvial soil in proportion to its length, estimated comparatively.

The banks of the Missouri and Mississippi are uniformly in a high degree productive, and contain perhaps one-third of all the valuable arable land of the state. The right shore of the Mississippi is, from Tewapaty bottom to the mouth of the Missouri, in most places, an enormous limestone wall. This distance is about 170 miles. This limestone is merely the buttress of the underlaying strata of the interior country. The Mississippi flows in a deep channel, whose sides are elevated near 200 feet above its highest surface. Those precipitous banks are continued in the Missouri. The rich alluvial bottoms are at the base of this limestone precipice, and no doubt derive much of their fertility from the calcareous *debris* that the abrasion of the waters, in past ages, have worn away and deposited below.

About one-third part of Missouri lies north of Missouri river, and west of Mississippi river. This, in point of soil, is much the best part of the state. It is more uniformly fertile, though less diversified in surface, than the section south of Missouri, and south-west of the Mississippi river. The northern section is also much chequered by small rivers, which generally flow south into Missouri, and though mostly forest land, some extensive and very productive prairies occur. South of Missouri, there exists no medium between the best and worst lands, and similar to all those parts of the United States below the Missouri, and west of the Mississippi, the good soil extends in lines mostly upon the alluvial banks of rivers, or along the margin of prairies, and, consequently, can never admit a dense and scattered population. This is not so much the case with the northern section; the farms will assume in that quarter something of the promiscuous extension over the face of the country, which is characteristic of settlements in the northern and eastern states.

Taken as a whole, Missouri, like most new countries in the United States, has been, as a body of arable land, greatly overrated. As a commercial position, if due allowance is made for its internal situation, the value of this section of our country has never yet been duly appreciated. The truly astonishing assemblage of rivers, which seem to have sought a common centre of union, would indicate St. Louis, or some other place in its vicinity, as the future *entrepot* between widely extended, and far distant portions of our empire. If the pursuits of mankind, and their individual means of subsistence, were exclusively agricultural, Missouri could never, in proportion to territorial extent, possess a population equally dense with New-York, Pennsylvania, Ohio, Indiana, or Illinois; but in the complex admixture of employment, and the illimitable transmission of the products of human labour, arising from the improvement of modern manners and arts, population does not depend for its entire subsistence upon the quality of the soil inhabited by any portion of mankind. Commerce and the plastic arts demand, perhaps, as many hands as agriculture. There is indeed no employment of human labour, where so great a surplus is produced as that of agriculture; and none, in which the industry of a few will so effectually supply the wants of many. It is for this reason that the density of population must, particularly in such places as Missouri, depend as much, if not more, upon commercial, mining, and manufacturing pursuits, as upon the operations or resources of agriculture. In addition to the apparently inexhaustible stores of lead ore, some of the most abundant iron mines in the world exist on the Missouri river, and in the interior of the state. In Washington county, Belvue settlement, in addition to lead, says Mr. Schoolcraft, "in the richness of the ore, and extent of the beds or mines, it is no where paralleled. The most noted place is the iron mountain, where the ore is piled in such enormous masses, as to constitute the entire southern extremity of a lofty ridge, which is elevated 500 or 600 feet above the plain." Water power to work this mass abounds in all directions. It is, however, only one of a number of mines of this really most precious of all metallic bodies, which lie scattered over the sources of St. Francis and Merrimack rivers.

In the same vicinity, and in fact over the entire lead tract, ores of zinc abound, a very important fact in the mineralogy of Missouri. Zinc is, when it can be cheaply procured, one of the most useful metals, answering nearly all the purposes, without the destructive qualities of copper. Zinc has been hitherto considered a scarce ore, and should it be found in large bodies in the Mississippi basin, will add a very important article to the resources of that fine region.

The most singular circumstance in the mineralogical history of the interior of North America, is the abundance and extent of the stores of muriate of soda, common salt. Amongst the revolutions effected in the last forty years on the condition of society, there is none more salutary to private convenience than the change in the price of salt in the interior of this continent. We remember, when the supply for west Pennsylvania and west Virginia was procured by transportation from the Atlantic slope. At a period when money was at least 100 per cent. above its present value, salt cost in those places five dollars per bushel, at a *minimum* price. It is now manufactured in a great variety of places, where the face of the earth gave no indications of its existence.

There is good reason to believe, that at certain depths, the whole basin of the Mississippi is saturated with salt water; a fact which, combined with the abundant existence of limpid fresh water at the surface, is highly consolatory.

Where muriate of soda prevails to such excess, as in some parts of the Spanish internal provinces, the earth becomes uninhabitable, cold, and steril. This is also the case with part of central Asia. In Europe, salt is procured generally from the sea, or found in substance in mines, as at Guadaloupe in Spain, and more particularly Wielitzka, near Cracow, in Austrian Poland. In North America, this mineral has not been found in solid imbedded masses, though no reasonable doubt can be entertained, but that the bowels of the earth must contain prodigious bodies of that fossil in its crystallized state, in places where it is so very extensively held in solution by water. It may be safely expected, that in some future day, muriate of soda will be quarried in the Mississippi basin, as in Spain and Poland.

Coal has been mentioned amongst the mineral products of Missouri; but we are unacquainted with any extensive body of that fossil yet brought into use in that state. Mr. Bradbury speaks with enthusiasm of the enormous strata of both coal and iron, which lines many parts of the banks of Missouri; but the coal spoken of by this author is generally above the limits of Missouri.

Many other mineral substances of less value have been discovered in Missouri; but so much of the area of the state remains unsettled, that its mineral and vegetable wealth have only commenced their development. From what is known, much may be expected; few sections of the earth, of equal superficies, and of so recent civilized colonization, have exhibited so rich a variety of mineral resources as southern Missouri.

This state is in a peculiar degree remarkable, as forming the connecting link between the forest and meadow or prairie sections of North America. That enormous forest, which we have remarked as covering the entire Atlantic slope, nine-tenths of St. Lawrence basin, all the basins of Appalachicola and Mobile, all the Delta of the Mississippi, and most parts of the left side of its basin, reaches into Missouri, and covers nearly all its southern and south-eastern sections. This great body of woods is indented in Ohio, Indiana, and Illinois, by a protrusion of the prairies, which expand advancing south-west, and range through Missouri south of Missouri river. On the west border of that state, on the Osage, and near the junction of the Missouri and Kanses rivers, the prairies usurp much the greater share of the surface of the whole country. Lines of woodland follow the streams, leaving the intermediate spaces open plains. Those lines of timbered ground gradually become more attenuated westward, until nearly one unbroken waste spreads over hundreds of miles. The peninsula between Missouri and Mississippi rivers, though not so naked of timber as are the sources of Arkansaw, Kanses, and Platte rivers, yet immense prairies occur on the former region also. Over an extent much more than equal to the inhabited parts of the United States and Canada, the winds of the north, west, and south-west breathe over Missouri, without much impediment from mountains, hills, or forests. It will be seen in the sequel, that from this exposure arises the peculiar variable and cold climate, which prevails near the junction of the Mississippi and Missouri rivers. If due attention is paid to the physiognomy of the adjacent regions, it will at once be seen, that the surface of Missouri is in a peculiar manner liable to extraneous influence. To the south-west, for upwards of twelve hundred miles, expands a dry salt desert. To the west, as far as known, the extension of the same desert leaves the earth a void. To the north-west, a two-fold cause superinduces a flux of cold air over Missouri. The openness of the immense regions in that direction, and the constant volumes of cold, and often frozen water, brought down by the Mississippi and Missouri rivers. It is from these combined causes that such excessive changes are felt, and inequalities of seasons experienced, to extremes scarcely known in any other spot on this planet. It is from this complicated climate, that in N. Lat. 38° 30′, the rivers are frozen, four years in five, before the end of December. Another phenomenon has been observed in Missouri, which in a striking manner distinguishes its seasons from those of Louisiana or the Atlantic slope; that is, the much less moisture in the atmosphere of the former. Though frosts are so rigorous at St. Louis as to render the Mississippi passable on the ice before the beginning of January in ordinary seasons, yet deep snow or drenching rains are uncommon. The air is commonly dry, cold, and elastic. In reality, the position of Missouri, Arkansaw, and Louisiana, are all singularly worthy of philosophic attention. A dense forest covers all the alluvial bottoms of the Mississippi, and those of its confluents. On the east side of that vast recipient, we have seen this forest only terminated by the Atlantic ocean. On the west, it is followed by the prairies or desert we have noticed. Moisture is as remarkably abundant in the forest tracts, as it is wanting in that of the prairies. The natural consequence of the position of places, on the confines of two regions whose meteorological constitutions are so essentially different, is an exposure to the extremes of both, following the current of air. This is, in an extraordinary degree, the case with Louisiana, where two successive seasons may differ so much, as one to present an almost constant deluge of rain, and the other scarcely affording a single shower. Ascending the Mississippi, the quantity of rain becomes less in a given time, at least as far north as 45°.

A remark may be made in this place, that what may be designated the rainy and dry seasons, are not confined to the tropics. Rain and snow are mere relative terms, therefore, in the United States. The rainy and dry seasons are nearly as regular in their succession and periods, as similar seasons are within the tropics. The difference is rather in the quantity, than in the times of rain and fair weather. To this theory, Louisiana is the most remarkable exception; and when viewed in connection with the adjacent and distant regions, the causes of the aberrations of the seasons of that state, are at once perceived, and clearly understood. It ought, however, to be recollected, that we are now making a natural, and not a political survey; therefore, in specifying Louisiana, the Delta of the Mississippi and contiguous places are meant. It is when making such expansive surveys, and elucidating the phenomena of nature on so large a scale, that the full value of maps can be fully appreciated. Without maps, no enlarged views of the laws of meteorology could ever be formed by any exertion of the human intellect; and it is from neglect of such comprehensive combinations, that so many crude notions on particular climates pass current.

Climate, Seasons, and Productions.—After what has been given in this article, little can be added on these heads.

The climate of Missouri is liable to great extremes of heat and cold. The winters at St. Louis are severe; the Mississippi, in ordinary seasons, being frozen before the end of December. The illimitable plains to the south-west and west of the state, leave an open vent to the winds, and superinduce a much greater severity of cold in a given latitude than on the Atlantic coast.

The seasons of Missouri partake of the unsteady character of the climate of the Mississippi basin, and indeed of the continent of North America in general. No two seasons in succession have much resemblance to each other. The occurrence of first frost in autumn, the last in spring, or the quantity and times of rain and snow in winter, are equally uncertain.

In one respect, the climate of Missouri differs essentially from that on the Atlantic slope in similar latitudes: as we before observed, less moisture falls on the former than on the latter, either as rain or snow. This circumstance has misled many as to the real nature of the climate of Missouri, and has given to it a character of mildness, the reverse of the fact.

The productions of Missouri have been noticed, both vegetable and metallic. We may merely add, that the vegetables usually cultivated, are those found in the middle states generally.

In metallic and other fossil substances, Missouri is perhaps the richest region in the United States. The following catalogue, given by Mr. Schoolcraft, yields a result, which strongly illustrates the mineral wealth of the state of Missouri, where most of these substances are found.

Metallic Substances.

Native iron,	Iron sand,
Red oxyd of iron,	Native magnet,

Argillaceous oxyd of iron,	Granular sulphuret of lead,
Micaceous oxyd of iron,	Earthy oxyd of lead,
Iron pyrites,	Carbonate of lead,
Brown hematite,	Sulphuret of antimony,
Sulphuret of zinc,	Black oxyd of manganese,
Sulphate of zinc,	Native copper,
Sulphuret of lead,	Sulphate of copper.

Saline Substances.

Nitrate of potash,	Sulphate of magnesia,
Muriate of soda,	Native alum.

Inflammable and Miscellaneous Substances.

Sulphur,	Madrepore,
Stone-coal,	Graphite.
Pumice,	

Earthy Substances.

Chalk,	Plastic white clay,
Flint,	Fullers' earth,
Hornestone,	Stalactite,
Rock-crystal,	Stalagmite,
Novaculite,	Pudding-stone,
Common quartz,	Opal,
Citrine,	Jasper,
Radiated quartz,	Agatized wood,
Red ferruginous quartz,	Carnelian,
Granular quartz,	Sulphate of lime,
Tabular quartz,	Feldspar,
Hoary quartz,	Calcareous spar,
Steatite,	Basanite,
Mica,	Buhrstone,
Chalcedony,	Onyx agate,
Reddle,	Greenstone porphyry,
Yellow earth,	Schorl,
Opalized wood,	Ochre,
Agaric mineral,	Shale.

To the above may be added carbonate of lime, in form of limestone, and marble.

The lead-mines of Missouri are principally in the county of Washington, but there are also diggings in St. Genevieve, Madison, and Jefferson counties.

The ore is that species called galena, by mineralogists; the sulphuret of lead, of chemistry. The ore yields about 80 per cent. of pure lead. The mass seems inexhaustible, but very irregularly disposed, the veins having no stratification, but branch through the other substances in every direction, and an indefinite thickness. Taken as a whole, the lead district of the state of Missouri is the richest in the production of that metal of any ever discovered.

Counties and Historical Epocha.—Bounded on the Missouri and the Mississippi, and occupying the north and west sections of the state, are the counties:

	Chief Towns.
St. Louis,	St. Louis.
Franklin,	Franklin.
Cooper,	
Howard,	
St. Charles,	St. Charles.
Montgomery,	
Pike,	
Lincoln.	

Those counties lying along the territory of Arkansaw south, and along the banks of the Mississippi east, are:

	Chief Towns.
Lawrence,	
New Madrid,	New Madrid.
Cape Girardeau,	Cape Girardeau.
Wayne.	

The mining district contains the central counties of

	Chief Towns.
St. Genevieve,	St. Genevieve.
Madison,	Fredericktown.
Jefferson,	Herculaneum, or St. Michael.
Washington,	Caledonia.

The lead mines of the state of Missouri deserve some historical notice, from their immensity and national importance.

The West Company was formed by letters patent under the regency of the duke of Orleans, during the minority of the king of France, Louis XV.; dated the 23d of August, 1717, and enregistered the 6th of September following.

Under this company, came out to Louisiana in 1719, Philip Francis Renault, son of Philip Renault, a noted ironfounder at Consobre, near Manberge, in France.

In 1720, Renault and one of his associates, a M. La Motte, discovered the respective mines which bear their names.

Renault worked the mines extensively, but was in the end obliged to abandon the undertaking, from some fiscal arrangements in France, and returned to his native country in 1742. From that period until 1797, or during the long period of 55 years, no attempts of any consequence were made to smelt lead in these neglected mines.

In 1797, a Moses Austin, Esq. from Wythe county in Virginia, made a journey to the lead mines in Louisiana, and obtained a patent from the Spanish authorities for one league square, in consideration of erecting a reverberatory furnace. This work was commenced in 1798. Mr. Austin sunk the first regular shaft for raising the ore.

In 1799, this gentleman erected a shot tower, and made shot of approved quality. The latter work was erected under the superintendance of Elias Bates. Since the foregoing period, the lead-mines have continued to attract public attention, and have been extensively worked. When Mr. Schoolcraft visited this tract in 1818, he enumerated forty-five diggings.

What is now the state of Missouri formed a part of Louisiana, and has underwent the political revolutions of that country, and was amongst the first parts that the French discovered. In 1674, two Missionaries, by the names of Jolliet and Marquette, entered the Mississippi by the route of Ouisconsin, descended the former stream to the Arkansaw, and returned to Canada by the Illinois. The country was visited by M. de la Salle in 1683. Some settlements were made soon after in the respective regions now comprised in the state of Illinois and territory of Arkansaw, but none in any part now within the state of Missouri.

In 1762, all Louisiana was ceded by France to Spain, and possession taken in 1769.

Upper Louisiana, now state of Missouri, began to be peopled about 1760. The attempt of settlement at the mines by Renault, and its failure, we have seen. In 1762, the present town of St. Louis was commenced, since which period settlements have gradually, but, during the existence of the Spanish government, slowly advanced. In 1803, this country, with all Louisiana, was ceded to the United States; and, early in 1804, was taken possession of by Major Amos Stoddard.

Louisiana was divided into two territories, that of Orleans below N. Lat. 31°, and Louisiana, containing the residue of that country. New Orleans continued the capital of Orleans, and St. Louis, of Louisiana.

In 1810, the then territory of Louisiana contained 20,845 inhabitants, of which 3011 were slaves.

In 1812, when the territory of Orleans became the state of Louisiana, Louisiana territory was changed to the territory of Missouri; and, on the 4th of January, 1813, Mr. Edward Hamstead took his seat in Congress, as delegate. April 3d, 1818, the bill for the admission of Missouri into the Union as a state received the second reading, and was committed.

On the bill being brought up for a third reading, its passage was opposed, unless under condition of prohibiting the introduction of Negro slaves. This opposition defeated the bill in the session of 1818—19, and in the session of 1819—20, both of which, particularly the latter, was in great part consumed in debates on the subject. In the former session, March 6th, 1820, an act was passed permitting the people of Missouri to elect a convention, which was empowered to frame a constitution, and adopt such name as they should choose; and under such constitution, when approved by Congress, such state to become one of the United States, with all the rights and immunities appertaining to the original states.

The convention of Missouri met at St. Louis, ——— 1820, and formed a constitution, which was presented to Congress for approval, at the opening of the session of 1820—21. A clause in the constitution, excluding from the state free negroes and people of colour, gave rise to a long and violent debate in both houses, which eventuated in a resolution of Congress, dated March 2d, 1821, in the following terms.

"*Resolved by the Senate and House of Representatives of the United States of America in Congress assembled*, That Missouri shall be admitted into this Union on an equal footing with the original states, in all respects whatever, upon the fundamental condition, that the fourth clause of the twenty-sixth section of the third article of the constitution submitted on the part of said state to Congress, shall never be construed to authorize the passage of any law, and that no law shall be passed in conformity thereto, by which any citizen of either of the states in this Union, shall be excluded from the enjoyment of any of the privileges and immunities to which such citizen is entitled under the constitution of the United States: *Provided*, That the legislature of the said state, by a solemn public act, shall declare the assent of the said state to the said fundamental condition, and shall transmit to the President of the United States, on or before the fourth Monday in November next, an authentic copy of the said act; upon the receipt whereof, the President, by proclamation, shall announce the fact: whereupon, and without any further proceeding on the part of Congress, the admission of the said state into this Union, shall be considered as complete."

The legislature of Missouri, on the 26th of June, 1821, passed an act of accession to the conditions contained in the foregoing resolution of Congress, and transmitted the act to the President of the United States, who, on the 10th day of August, 1821, issued his proclamation pursuant to the tenor of the resolution of Congress, and the accession of the legislature of Missouri to its provisions, and Missouri became a state of the United States.

It may not be uninteresting to trace the line, which, by the act of admission of Missouri, bounds the slave-holding from the non-slave-holding states and territories that have been, or may be formed beyond the Mississippi. Beginning on the right bank of that stream, at the mouth of Ohio, and following the boundaries of the state of Missouri up the Mississippi and Lemoine rivers, and thence to the south-west angle of Missouri, on the north boundary of Arkansaw territory, at N. Lat. 36° 30′; and thence due west to the frontier line between the United States and Spain.

MITHRIDATES. See ROME.

MITYLENE. See METELIN.

MNEMONICS (*ars mnemonica*, from the Greek *μνημων*, *memor*,) signifies, in the more general sense of the word, the laws which regulate the exercise of the faculty of memory; in its more limited signification, it means a system of rules to assist the memory, by means of association, in recalling past impressions. Such a system was called by the ancients *memoria artificialis*, to distinguish it from a naturally good memory, unassisted by technical rules.

There is no doubt that the memory is a faculty highly susceptible of cultivation, and also very capable of being assisted, in many cases, by arrangement and association. We have numerous instances, indeed, both in ancient and modern times, of individuals who possessed and exercised this faculty in a very extraordinary degree; but we are frequently left in doubt whether they depended entirely on the natural strength of an originally good memory, improved, perhaps, by regular and assiduous cultivation; or whether they had recourse to some mechanical aids. Cyneas, who was sent by King Pyrrhus on an embassy to the Romans, learnt, in the course of one day, the names of all those persons whom he had seen so perfectly, that, on the following day, he could name all the members of the senate, and all the Romans who had assembled round them. King Cyrus could name all the soldiers in his army; and L. Scipio all the citizens of Rome. Mithridates, the king of two and twenty nations, held courts in as many languages, and could converse with each nation in its own tongue, without using an interpreter. Themistocles is said to have been oppressed by the strength and tenacity of his memory; and in the course of a year he learnt to speak Persic with perfect propriety. Crassus, while governor of Asia, learnt the five Greek dialects so completely, that he was able to give judgment in each. Hortensius, the Roman orator, was able to repeat a whole oration in the words he had previously conceived it, without committing it to writing; and to go through the whole arguments of an opponent in their proper order. It is said, that he once attended a whole day at a public sale, and, at the end of it, recited, in regular order, the names of all the buyers, the articles sold, and their prices, with perfect exactness. Seneca, in his youth, could pronounce two thousand given words in their proper order; and having got a verse from each of his school-fellows, he repeated more than two hundred of them from the bottom to the top. Avicenna could with facility repeat the whole books of Aristotle's metaphysics. Picus de Mirandola repeated two thousand names which had been read over to him. Joseph Scaliger, when a young man, could repeat above one hundred verses, having once read them; and, in the course of a few weeks, he could repeat the contents of whole books in foreign languages. Magliabechi dictated, from memory, whole books which had been lost. Several individuals are said to have been able to repeat the contents of entire books from the end to the beginning, as is reported of the German poet Klopstock, with respect to Homer, when he was at the school of Porta. William Lyon, a travelling player, repeated the contents of a newspaper from beginning to end. An Englishman once came to Frederick the Great of Prussia, for the purpose of giving him some specimens of his extraordinary memory. Frederick sent for Voltaire, who read to his majesty a pretty long poem which he had just finished. The Englishman was concealed in such a manner as to be able to hear every word that was said. When Voltaire had concluded, Frederick observed that a foreign gentleman would immediately repeat the same poem to him, and therefore it could not be original. Voltaire listened with astonishment to the stranger's declamation, and then fell into a great rage, and tore the manuscript in pieces. When Frederick informed him of his mistake, the Englishman again dictated to Voltaire the whole poem with perfect correctness.

These instances are sufficiently remarkable, even after making every reasonable allowance for exaggeration. But there is a story told by Antonius Muretus, respecting the wonderful memory of a young Corsican, which is still more astonishing. We shall relate the story nearly in his own words. "At Padua there dwelt, not far from me, a young Corsican, who was believed to be of a good family. He had come thither in order to learn the civil law, and had devoted himself, for several years, to this study, with such diligence and success, that we all began to entertain a high opinion of his learning. During one summer, he came almost every evening to my house. He was reported to be in possession of an art of memory, by means of which he could perform things which no one could believe without being an eye-witness. I had scarcely learnt this when I became desirous of seeing some of these wonders; and my wish was soon gratified. I told him that, in return for my hospitality, I conceived I had a right to ask to see a specimen of his art, if it were attended with no inconvenience to himself. He answered immediately, and without taking time to reflect, that he would willingly comply, as soon as I should desire it. We went directly into an adjoining room, and sat down. I dictated to him words from the Latin, Greek, and other languages, with which he was less familiar, sometimes with and sometimes without meaning, so different, so unconnected, and in such number, that I was abundantly fatigued with dictating, the boy who took down the words with writing, and the other persons present, with hearing and expectation of the result. He alone, still cheerful and unexhausted, always called for more. I told him, however, that every thing must have its due measure and limits, and that I should be perfectly satisfied if he could repeat but the one half of what I had dictated. He then stood for some time silent, with his eyes fixed upon the ground, while we were all full of expectation. At length this wonderful man began to speak; and he repeated, to our astonishment, every thing in the very same order, and without the slightest embarrassment or hesitation. He then began with the last word, and repeated backwards to the first; and he afterwards repeated the first, third, fifth word, &c. or in any other given order. I afterwards became better acquainted with him, and found, after many trials, that there was no quackery in his system. He once assured me (and he was the greatest enemy of all boasting) that he could, in the same manner, repeat 36 000 (others read only 6.000) words. But what is most remarkable, every thing was so firmly impressed on his memory, that, as he asserted, he could without difficulty remember whatever he had committed to it after a lapse of years; and this assertion I found to be true, upon making a trial some considerable time afterwards. But farther: There dwelt with me Franciscus Molinus, a patrician of Venice, who was exceedingly ardent in the study of the sciences. Impressed with the feeling of the weakness of his memory, he entreated the Corsican to teach him his art, to which the latter immediately consented. A place and hour were accordingly fixed for their daily meetings; and in the course of six or seven days the scholar could repeat, without difficulty, more than five hundred words, in the same, or any other given order." Muretus adds, "I should not have ventured to relate all this, lest I should be suspected of a falsehood, if the facts had not been quite recent, and capable of being attested by a number of witnesses. The Corsican asserted that he had learnt this art from a Frenchman, who had been his tutor." Gisbert Voetius, a reformed divine of the seventeenth century, considers the performance of this Corsican as a proof of his intercourse with the devil.

The astonishing powers of calculation possessed by Jedediah Buxton, a man otherwise illiterate, are well known; and many of us have had a recent opportunity of witnessing a similar phenomenon, in the person of Zerah Colburn, an American boy, under eight years of age, who exhibited in London and Edinburgh some years ago, and who, without any previous knowledge of the common rules of arithmetic, or even of the use and power of the Arabic numerals, and without having given any particular attention to the subject, was found to possess, as if by intuition, the singular faculty of solving a great variety of arithmetical questions by the mere operation of the mind, and without the usual assistance of any visible symbol or contrivance.*

We might quote various other instances of individuals who possessed extraordinary powers of memory, but it is unnecessary to multiply examples. We proceed, therefore, to notice the traditional origin of the mnemonic art, as mentioned in the Parian Chronicle, as well as by Cicero and Quintilian, and other ancient authors. And here we shall avail ourselves of the labours of the late Professor Barron, who, in his *Lectures*, has entered pretty fully into the discussion of this subject.

The principal expedient for assisting the memory is

* George Bidder, a boy from Devonshire, has exhibited powers of calculation not inferior to those of Zerah Colburn. He is now educating in Edinburgh, under the patronage of Henry Jardine, Esq. See the *Edinburgh Philosophical Journal*, Vol. II. p. 193.—Ed.

derived from association. For instance, when I see a house, I naturally recollect the inhabitants, their manner of life, and the intercourse I have had with them. The sight of a book prompts the memory of its contents, and the pleasure or profit I have received from the perusal of it. A view of the sea may suggest the idea of a storm; and the painful recollection of the loss of property, or of the life of a friend, by shipwreck. The act, then, of aiding recollection by association, is to connect thoughts remote or abstract, with others more obvious and familiar, that the recurrence of the latter may bring along with it the memory of the former. Thus, the sight of my ring, which I cannot miss to observe, reminds me of the action, to suggest the remembrance of which I removed it from one finger to another. The ringing of the bell, or the sounding of the clock, prompts the recollection of the business I had resolved to perform at these times. A glimpse of the first words of a paragraph, or a page, introduces the recollection of the whole. In a word, we must connect the things we wish to remember with the immediate objects of our senses, that offer themselves daily to our attention, but particularly with the objects of our sight, the most vigorous and lively of all our senses, and of which the objects are perhaps more numerous than those of all our other senses put together.

This theory is the foundation of all contrivances which have been, or perhaps can be, employed to help recollection. It is the groundwork of the famous artificial memory of Simonides, a lyric poet, who is celebrated by Cicero and Quintilian as the inventor of mnemonics. Both these authors relate the following mythological incident, on the occasion which suggested the invention. Simonides was employed by Scopas, a rich Thessalian, to compose a panegyric on him for a certain sum of money; was invited to a festival, given by Scopas to his friends, in order to rehearse it, but was sordidly refused more than half the stipulated compensation; because, puzzled perhaps with the sterility of the principal subject, he had introduced a long episode in praise of Castor and Pollux. Simonides was soon after summoned from the company by two young men on horseback, supposed to be Castor and Pollux in disguise, who, as soon as they had saved their favourite poet, made the roof fall on Scopas and his company, bruising them to death, that not a lineament of them could be known. Simonides, however, by recollecting the order in which they sat at table, was enabled to distinguish them, and to deliver them to their friends for burial. The aid which the recollection of the poet received, on this occasion, is said to have suggested the idea of an artificial memory.

The principle of the scheme of Simonides is, to transfer a train of ideas, the archetypes of which are not the objects of sense, and are, therefore, of difficult recollection, to another train which we cannot fail to recollect, because the archetypes are not only objects of sense, but objects of sight, with which archetypes we are perfectly familiar, or which may be placed actually before our eyes. Suppose then Simonides were to commit to memory a discourse consisting of speculations concerning government, finances, naval affairs, or wisdom, none of the archetypes of which could be made objects of sense, at least, at the time of delivery; and to assist his recollection, he were to connect the series of ideas, in that discourse, with a series of objects, which he could either place in sight, or with which he was so familiar that he could not fail to recollect them; he would proceed in the following manner: He would take a house, for instance, either the one in which he might deliver the discourse, or another; with every part of which he was perfectly acquainted. He would begin at some fixed point of that house, suppose the right side of the door, and he would proceed round it in a circular line, till he arrived at the point from which he set out. He would divide the circumference of the house into as many parts as there were different topics or paragraphs in the discourse. He would distinguish each paragraph by some symbol of the subject it contained; that on government by the symbol of a crown, or a sceptre; that on finances, by the symbol of some current coin; that on naval affairs, by the figure of a ship; that on wisdom, by the figure of the goddess who presided over it. He would either actually transfer, or suppose transferred, these symbols to the different compartments of the house, and then all he had to do, in order to recollect the subject of any paragraph, was, either to cast his eye on the symbol during delivery, or to remember upon what division the symbol was placed. The memory, by this contrivance, easily recalled the discourse. The orator either saw, or could not fail to remember the compartments, because he was perfectly familiar with them. Neither could he forget the symbols of each paragraph, because they were no more than hieroglyphical paintings of the sense.

Such were the origin and principles of the celebrated topical memory of the ancients; from which source are derived all the various modern systems of local and symbolical memory. Our readers will find this story of Simonides circumstantially related and commented on by Cicero, *de Orat.* lib. ii.; by the author of the books *ad Herennium*, lib. iii.; and by Quintilian in the second chapter of the eleventh book of his Institutions. The Anthology has preserved the following distich of Simonides, relative to the subject of his memory:

Μνημην δ'ȣ τινα φημι Σιμωνιδη ισοφαριζειν
Ογδωκοντα ετει παιδι λεωπρεπεος.

Nemo magis memor est Simonide, conscius aio
Cui sex et fuerant lustra peracta decem.

We must observe, however, that in spite of these ancient authorities, the claim of Simonides to the merit of inventing the art of memory, has been recently controverted in a dissertation on the mnemonic art among the ancients, by Professor Morgenstern of Dorpat, who seems to trace this science to the Egyptian hieroglyphics.

Several of the Greek philosophers appear to have adopted and recommended certain artificial rules for the assistance of the memory; Aristotle is said, among others, to have written a work entitled *Μνημονικον*, which has been lost; and Pliny (*Hist. Nat. Lib.* VII. *cap.* 24.) expressly names Metrodorus, a contemporary of Cicero, as the individual who first brought the art into a systematic and scientific form. It is to him, therefore, that we are probably indebted for the theory of places and images.

In more modern times, this art was cultivated by Raymund Lully, (in his *Ars Magna*,) and others, whose works we shall notice at the end of this article. The Germans, who are fond of constructing theories upon all subjects, have recently paid much attention to mnemonics, and have not only explained the ancient methods, but invented several new systems.

So early as towards the end of the 16th century, the art of memory was revived by Lambert Schenckel, a man who possessed considerable learning, and who wrote various works on grammar, prosody, rhetoric, &c. He travelled for many years in Germany, the Netherlands, and France; and he obtained from the University of Paris the privilege of teaching his mnemonic doctrines in that capital. In his old age, he appointed his friend and pupil, Martin Sommer, a Silesian, to be his successor in the mnemonic chair. Sommer published a short tract in Latin, by way of invitation to the study of his art. Like his master, Schenckel, he travelled a great deal, and realised a considerable fortune by teaching. Schenckel's work on the art of memory appeared, for the first time, in 1610; and Sommer published a new edition of it in 1619. For a long period, the principles of Lullus and Schenckel continued to be studied and commented upon, but little accession was made to the doctrine of mnemonics; on the contrary, the speculations on this subject degenerated so much into frivolous commonplace, or mystical jargon, that they tended rather to degrade than to promote the study of the art.

The principal work published in England, on the subject of the local memory, appeared in 1618, under the title of *Mnemonica; sive ars reminiscendi*, &c. by John Willis; and was translated, in 1661, by one Sowersby, a bookseller. In the year 1651, Henry Herdson published his *Ars Mnemonica, sive Herdsonus Bruxiatus*, &c. in Latin and English. It is merely a republication of part of Brux's *Simonides Redivivus*. The *Memoria Technica* of Richard Grey was published in 1730; and to the ninth edition are appended the *Mnemonics* of Solomon Lowe, a small tract, now exceedingly rare, which was first published in 1737. The system of Dr. Grey is allowed to be very ingenious. Dr. Priestley observes, "It is so easily learned, and may be of so much use in recollecting dates, when other methods are not at hand, that he thinks all persons of a liberal education inexcusable, who will not take the small degree of pains that is necessary to make themselves masters of it; or who think any thing mean, or unworthy of their notice, which is so useful and convenient."

Since the commencement of the present century, the mnemonic doctrine has been again revived on the Continent, with considerable success, by Gräffe, Aretin, Duchet, Kästner, Feinaigle, and others. Feinaigle travelled a good deal; and some years ago, he taught, and exhibited specimens of his method, at Paris, London, and Edinburgh. A small volume was afterwards published, illustrative of the principles of his system, and exhibiting their application to the various sciences; from which we shall endeavour to present our readers with an abridged account of his method.

Locality, it is observed, is the most efficacious medium of reminiscence; and that system of memory will be the most serviceable which brings this principle into the most extensive operation. For this reason, *locality*, or the connection of our ideas with places, is made the foundation of the present system.

A room having generally four walls, the most obvious division of it is into four sides, and each wall or side may be subdivided into pannels or compartments. Accordingly, the ancient system divided a wall into five spaces; and this plan was applied to as many rooms as were found necessary to the extent of each particular scheme —every room being similarly divided into four sides, and every side being subdivided into five compartments. Thus, any idea which, according to this method, had been associated in the mind with the forty-eighth compartment, would be placed in the third compartment of the second wall, in the third room. But, as few compartments could be obtained on each wall by these means, the calculation of high numbers would be exceedingly difficult. To remedy this defect, each wall might be divided into nine or ten compartments. If a wall be divided into nine parts, there will be 36 compartments in every room. In order to ascertain the situation of any particular number, it is to be considered in relation to the total number of the subdivisions. For example, if the situation of number 48 be required; according to the last mentioned division of the rooms, it is to be found by considering the proportion which that number bears to 36, the total number of the compartments in this arrangement. If the number in question be less than this total, the place inquired after will be obvious; thus, 12 being within the number 36, must, of necessity, be in the first room; being above 9, it is equally clear that in cannot be on the first wall, and being less than 18, it must, necessarily, be in some part of the second wall; and as it exceeds the number of the first wall by 3, it follows, of course, that its place must be in the third compartment of the second wall. If the number in question be higher than the number of the compartments in one room, its place will be readily found by dividing it by that number. Thus, suppose 48 to be the number whose place is required:

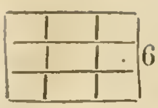
```
36)48(1.2
   —
 9)12(1.2
   —
    3
```

As 48 exceeds 36, we know that it cannot be in the first room, the 1 is therefore changed into two; and the fraction remaining shews it to be in the twelfth compartment. There being nine compartments in every wall, this remainder, or number of the compartments, is divided by 9, for the purpose of ascertaining the wall. Now, as the divisor is contained more than once, but not twice, in the dividend, it follows, that the compartment sought must be on the second wall; the remainder gives the specific compartment. This operation, then, shews that 48 is in the third compartment, on the second wall, in the second room. This was the plan adopted by the ancients, when they divided their rooms into parts; but being both complicated and difficult, Mr. Feinaigle has rejected it in his system; and another scheme has been introduced in its place, which he conceives to be more simple in its construction, less difficult in its application, and much more extensive in its powers.

He divides a wall in the following manner:

1	2	3
4	5	6
7	8	9

These figures are arranged from left to right, in the usual manner of writing; and for the more easily remembering their situation, it will be found, that if two lines be drawn diagonally from the four corners of the figure, they will intersect all the odd numbers. The nine squares, or compartments, are termed *places*, and are called first place, second place, &c. The same mode must be pursued with the three remaining walls in this room, by which means four walls are obtained, each divided into nine *places*. In order to find the number 36 in this room, we should naturally say four times nine will be 36, and should, of course, conclude that 36 would be in the last place of the last side or fourth wall of the room. But this calculation is erroneous; 6 must ever be in the same situation, which will be that occupied by the point in the following figure:



And the numbers 16, 26 and 36, will be in the corresponding situation on their respective walls.

It must now be determined, how we are to reckon these walls. If we stand in a room with our back to the windows, the first wall is on our left, the second before us, the third on our right, and the fourth behind us. We shall, however, commence with the floor, and divide it into nine parts, in the same manner as the walls. Where are 10, 20, 30. &c. to be placed? Every decade begins a new series, and the decimal is placed on the ceiling of the room over its proper wall; thus the first decimal, or 10, will be over the first wall; the second decimal, or 20, over the second wall, &c.; and the fifth decimal, or 50, as its tenth-part exceeds the number of walls, will be assigned to the ceiling of the room, and will consequently be the highest number in the first room, forming the connecting link between this room and the second. When a second room is taken, the floor of it is denominated the fifth wall, the wall on the left the sixth, &c., and as the number 50 was upon the ceiling of the first, so the number 100 will be upon the ceiling of the second room.

In order to remember a series of words, they are put in the several squares or places, and the recollection of them is assisted by associating some idea of relation between the objects and their situation; and, as we find by experience, that whatever is ludicrous is calculated to make a strong impression upon the mind, the more ridiculous the association the better. To illustrate this idea, Mr. Feinaigle places the names of certain sensible objects in the different compartments, and connects the ideas of their images by some story, so as to make it almost impossible to forget the order in which they are arranged.

Another part of Mr. Feinaigle's system is the converting figures into letters,—a branch of the mnemonic art which has been adverted to, we believe, by almost every writer on the subject. Mr. Feinaigle uses the consonants only, one or more of which are attached to the series of figures, each figure having its appropriate consonant. The letters appropriated to the figures are selected on account of some real or supposed resemblance. These letters, and the figures which they are intended to represent, should be strongly impressed upon the memory, as the letters must be converted into words by the introduction of vowels. The two consonants representing two figures must be converted into a word, to which should be affixed some striking idea; and the images represented connected together. The objects, when selected, each being a word, must be arranged in the different *places*, beginning with the floor, and proceeding to the first, second, and third walls, &c. In making these words, it is necessary that the two consonants required should be the two *first* in the word; if there be more than two, it is of no importance, as the two first only will be needful. The converting of figures into letters, and making sense by the introduction of vowels, will be found applicable to many of the purposes of common life.

Mr. Feinaigle proceeds to observe, that if the reader has practised the instructions already given in a room in which he is accustomed to spend the greater part of his time, and this room should have been hung with pictures, engravings, &c., he will have been very materially assisted in the remembrance of his *places* or localities. The transition is slight, but the impression is permanent. Let us, says he, fill the squares or places with some pictures of our own drawing; the two rooms will be then furnished, and it will be as easy to remember the symbols or hieroglyphics, as to remember the situation or place of any picture, or article of furniture, in a room. Mr. Feinaigle has, accordingly, illustrated this part of his system by some tables of symbols, and some diagrams, for which we must refer the reader to the book itself; as it has been our object rather to give an outline of his principles than a full exposition of his method. For the same reason, we deem it unnecessary to accompany the learned professor in his application of these principles to the various sciences.

We have already admitted the possibility of giving great assistance to the memory by means of arrangement and association. It appears to us, however, that the apparatus of most of the systems hitherto proposed with that view is a great deal too complicated; and that a method might be devised much more simple in its elements, more easy of acquisition, and equally well adapted to all purposes of real utility.

The following are the principal works which have been written on the subject of mnemonics: *The Castel of Memorie*, &c. *made by Gulielmus Gratarolus; Englyshed by William Fulwood.* (Black letter.) Gratarolì's treatise on the Memory was also translated into French by Stephen Cope; Lyons, 1586. Jordano Bruno, *De Imaginum et idearum compositione ad omnium inventionem, et Memoriæ genera tres libri;* Franc. 1591, 8vo. *Ars Reminiscendi Joan. Baptistæ Portæ Neapolitani;* Naples, 1602, 4to. Lambert Schenckel, *Methodus de Latina Lingua intra 6 mensis docenda*, Strasburgh, 1609, 8vo. Ejusd. *Gazophylacium Artis Memoriæ*. &c. Ibid. 1610, 8vo. Various other works were published in illustration of Schenckel's method. *Simonides redivivus*, &c. *Authore Adam Bruxio;* Leipsic, 1610, 4to. *F. M. Ravellini Ars Memoriæ*, &c. Franc. 1617. 8vo. John Willis, *Mnemonica*. &c. London, 1618. This book was translated into English by one Sowersby, London, 1661. *Ars Memoriæ localis*, &c. Leipsic, 1620, 8vo. Adrian le Cuirot, *Magazin des Sciences, ou vray l'art de Memoire;* Paris. 1623, 12mo. Henry Herdson, *Ars Mnemonica*. &c. in Latin, and *Ars Memoriæ; The Art of Memory made plaine*, in English; both tracts published at London, 1651, 8vo. Jean Belot, *L'Oeuvre des Oeuvres*, &c. Lyons, 1654, 8vo. Athanasius Kircher, *Ars Magna Sciendi*, &c. Amsterdam, 1969, fol. *The Divine Art of Memory*, &c. translated from the Latin of the Rev. John Shaw, by Simon Wastel, Lond 1683, 12mo. Buffier, le Pere, *Pratique de la Memorie Artificielle*, &c. Paris, 1719—1723, 3 vols 8vo. *Memoria Technica*, &c. by Richard Grey, D D. London 1730, 8vo. Solomon Lowe, *Mnemonics Delineated in a small compass*. &c. London, 1737, 8vo. This tract was reprinted in a late edition of Grey's *Memoria Technica*, D G. Morhof *Polyhistor*, &c. edit. quart. Lubeck, 1747, 2 vols. 4to. Fr. B. J. Feyjoo, *Cartas eruditas y Curiosas;* Madrid, 1781, 5 vols. 4to. D. J. L. Kluber; *Compendium der Mnemonik;* Palm. 1804, 4to. Graffe, *Katechetisches Magazin;* Gottingen, 1801, 8vo. J C. von Aretin, *Denkschrift über den wahren Begriff und Nutzen der Mnemonik*, &c. Munich, 1804 8vo. Ejusd. *Systematische Anleitung zur Theorie und Praxis der Mnemonik*, &c Sultzbach, 1810, 8vo. C. A. L Kästner, *Mnemonik; oder System der Gedächtniss—Kunst der Alten*, &c. Leipsic, 1804, 8vo. Ejusd. *Leitfaden zu* *seinen Unterhaltungen uber die Mnemonik*, &c. Leipsic, 1805, 8vo. *The New Art of Memory, founded upon the Principles taught by M. Gregor von Feinaigle*, &c. London, 1812. Of this work a second edition, with additional illustrations, was published in 1813.

MOBILE, a river of the United States of North America, in the state of Alabama, is formed by the united streams of Tombigby and Alabama rivers. The extreme north-west sources of Tombigbee are in the state of Mississippi, near the south line of Tennessee, from whence the different branches flow south-east into Alabama, where, uniting, they form the Tombigbee, which flows nearly due south to its junction with the Alabama, at N. Lat. 31° 05′. The Tombigbee receives, besides many lesser confluents, the Tuscaloosa, or Black Warrior, a large stream from the north-east. The entire length of the Tombigbee is about 300 miles, by comparative course.

The Alabama is formed by the united streams of the Coosa and Tallapoosa, which both rise in Georgia, and flowing to the south west, unite at N. Lat. 32° 23′, and from thence to the junction with Tombigbee assumes the name of Alabama. The entire length of the Alabama, from the sources of the Coosa to the head of Mobile river, is, by comparative course, about four hundred miles. A considerable branch from the north, called the Cahaba, enters the Alabama about one hundred miles, by the windings of the stream, below the junction of the Coosa and Tallapoosa. Cahaba, the seat of government for the state of Alabama, is situated at the mouth of the Cahaba river.

The river Mobile is about forty miles in length, from the head of Mobile bay to the junction of the Tombigbee and Alabama rivers. Within a very short distance of its head, the Mobile divides into two branches, that of Mobile proper to the west, and Tensaw to the east. These never again reunite, but flow separately into Mobile bay, with several inlets from one to the other. The islands enclosed between the main branches and the inlets are, in general, liable to inundation.

The Mobile river admits vessels of twelve feet draught in all its length; the Tombigbee, those of five feet to Fort Stoddart; and Mobile, those of about six feet to Fort Claiborne.

MOBILE Bay, opens below the mouth of the Mobile and Tensaw rivers, and gradually widens from four to ten or twelve miles, and, extending thirty miles nearly south, again contracts to about five miles, having Dauphin Island in nearly the middle of its entrance into the gulf of Mexico. The main channel, between Dauphin Island and the Point of Mobile, has a depth of about 18 feet. The channel between the main shore and Dauphin Island, known by the name of the Pass au Heron, has only six feet. A bar of thirteen feet water crosses Mobile bay three miles below the town of that name.

MOBILE Point, is a long, low, sandy, and narrow peninsula, which bounds Mobile bay on the south, extending from the bay of Bon Secours, the south-eastern extremity of the former, towards Dauphin Island, towards which it approaches to within three miles. This point has been rendered remarkable, by the erection of a military post on its extreme west extension, called Fort Bowyer.

This fort was attacked, September 15th, 1814, by a British squadron, consisting of two vessels of 28 guns each, and one of 18 guns, with a land force of 200 Indians, and 110 marines. The British were repulsed, with the loss of the Hermes, and about one hundred men killed and wounded.

After their defeat at, and retreat from New Orleans, the British attacked and took Fort Bowyer, on the 15th of February, 1815.

MOBILE Town, is situated on the west or right shore of Mobile bay, near the mouth of Mobile river, upon a bank elevated eighteen or twenty feet above the surface of the water in the bay. Mobile contains about two hundred houses and one thousand inhabitants. It is a place of considerable trade, though the entrance to the harbour is inconvenient for vessels drawing more than eight feet water. A long, narrow, and low island lies before the town, and extends about five miles above, round which large vessels are obliged to pass in order to reach the harbour, in which any vessel can enter in safety which can pass the bar, three miles below the island.

Mobile is situated at N. Lat. 30° 44′, and W. Long. from Washington City, 10° 55′, and from Greenwich, 87° 55′. Darby.

MOCHA, or Mokha, a maritime town of Arabia Felix, on the eastern coast of the Red Sea, is situated in the midst of a barren plain, about 15 miles north from the Straits of Babelmandel, in 13° 16′ N. Latitude, and 43° 11′ 15″ E. Longitude. It is placed between two low points of land, which project from the shore, so as to form a bay capable of sheltering such ships as can approach within a mile of the shore. On each of these points, which are about five miles distant from each other, is constructed a circular castle, built of stone, and provided with artillery, (either of which a British ship of war would level with the ground by a single broadside;) and nearly in the centre of the walls of the town, fronting the sea, is a similar fort, protecting the only gate in this quarter for the entrance of goods and passengers. From this gate a pier of stone runs out in a due westerly direction for the space of 150 yards, which was built about the middle of last century, by Captain Watson, superintendant of the Bombay Marine. The town itself stands so close to the shore, that during a westerly wind the sea washes against the walls, and is about a mile and a half in length from north to south, and half a mile in breadth. It is completely surrounded with walls of hewn stone, about 16 feet high on the sea-side, but about 30 in some places on the land-side, which are generally kept in good repair, and provided with loop-holes for arrows or musketry at the distance of every five feet. There are also batteries at each end of the town, and round towers on the walls at equal distances. But the walls are too thin to withstand a cannon ball, and the batteries scarcely able to bear the firing of their own guns. The houses fronting the sea are very lofty, built of stone, and all white-washed. There are several mosques in the place, the minarets of which rise to a considerable height, and the largest of them serves as a landmark to ships entering the road, particularly as a steering point to avoid the dangerous shoal, which begins about four miles from the shore, and reaches nearly to the pier-head. There are several tombs or square edifices, covered with circular domes, which break the uniform line of the flat-roofed houses, and altogether the appearance of the town, when seen from the roadstead, is striking and handsome. But the expectations of the stranger are completely disappointed as soon as he enters the gates, when he sees the streets covered with filth, and full of vacant spaces, or the ruins of deserted habitations. The principal building in the town is the residence of the Dola, a large and lofty structure with turrets on the top, and a variety of fantastic ornaments in white stucco. One front of it looks towards the sea, and another into a square, the only regular place in the town where the Dola and his officers amuse themselves in throwing the jerid. The best houses look towards the sea, and are chiefly situated to the north of the sea-gate. They are mostly built of brick made by the heat of the sun, and, unless carefully preserved from the access of moisture, are soon reduced to a heap of mud. The windows are generally small, placed regularly in the walls, and seldom capable of being opened for the admission of fresh air. The floors as well as the roofs of the larger houses, are made of chunam, laid on pieces of plank or thin sticks, closely arranged like laths across the beams, but are extremely uneven, a circumstance which occasions less inconvenience where neither chairs nor tables are used. The internal structure of the habitations is uniformly bad, the passages long and narrow, and the stairs so steep as to be ascended with difficulty. The lower orders live in huts, composed of wicker work, covered on the inside with mats, and sometimes on the outside with a little clay, the roofs of which are uniformly thatched, and each of which has a small yard fenced in front. The suburbs are situated to the south of the town, with a large vacant space between them and the walls, and contain as many inhabitants as the city itself, but chiefly of the poorer classes. One quarter is occupied by Jews, another by prostitutes, a third by the public slaves, who are mostly Abyssinians, employed in repairing the buildings or loading the vessels belonging to the government, and the other districts, by labourers, artisans, and a few gardeners, who, by means of great industry and plenty of manure, contrive to raise a little sallad, pulse, and sweet potatoes. The amount of inhabitants, both within and without the walls, is not supposed to exceed 10,000.

The climate of Mocha is extremely sultry, in consequence of its vicinity to the arid sands of Africa, from which the south-east winds blow above eight months in the year, and often with such violence as to prevent all communications between the shore and the vessels in the road. During other three or four months, the opposite monsoon blows from the north-west with less violence, but with still greater heat. The country in the vicinity of Mocha is remarkably dreary, and, for a circuit of ten miles, consists of arid sand, covered by a saline efflorescence, and with scarcely any appearance of vegetation, except the common mimosa, and a species of salicornia; but near to the town are numbers of date-trees, of stunted growth, and a few patches of vegetables in the neighbourhood of the wells. The town, however, is well supplied with provisions from the inland districts and the opposite coast of Abyssinia, and in summer great abundance of excellent fruits are brought from the adjoining country from 20 to 50 miles distance. The water is brackish and unwholesome to strangers, but pure water is brought daily to market from Moosa, a town about 20 miles inland.

About the end of the 14th century Mocha was not in existence, but, about the end of the 16th, it had become the great mart for the trade between India and Egypt, and about 1738 it seems to have reached its greatest height of prosperity, when the English, French, and Dutch, carried on a regular trade with it, by the Cape of Good Hope, for the coffee which used formerly to go by Suez across Egypt to Alexandria. This article, which is the principal produce of the country, together with gum-arabic, myrrh, and frankincense, which are brought from the opposite coast of Africa, form the greater part of the export trade of Mocha, and of which the larger portion still goes up the Red Sea to Suez. The imports are very considerable, particularly from India and Muscat, the greater part of which traffic is carried on through Banian traders from Surat, who are found in great numbers at Mocha, and are indulged with the public exercise of their religion.

Mocha, as well as the other towns belonging to the Imam, is governed by a Dola, who is usually a slave, who can be removed at pleasure, and made to disgorge the profits of his government, which are very considerable, and arise from the sums levied upon the Banians and other foreign merchants. The second officer in the town is the Bas Kateb, or Secretary of State, who is always an Arab, and considered as a licensed spy over the Dola. The third is the Cadi or Judge, and these three compose the divan, where all public business is conducted, and where the Dola has only a vote along with the rest. The police is very strict during the night, and any person found out of his house after the Dola has retired to rest, which is indicated by the drums beating before his door, would be conducted to prison. The garrison generally consists of about 80 horsemen and 200 foot soldiers, armed with match-locks and crooked daggers. These troops have no appearance of discipline or of warlike habits, and, when on guard at the different gates, are seen reclining on couches, with their matchlocks lying neglected by their sides, and a cup of coffee or smoking-pipe in their hands. They attend the Dola every Friday on his procession to the great mosque, and are afterwards exercised in the front of his house: they are tolerably good marksmen, but require a long time to take aim.

The food of the lower ranks of Arabs consists of a coarse grain raised in the country, juwarry, ghee, dates, and fish, which last article is very abundant and excellent. The crabs, particularly, are uncommonly large and plentiful, some of them not less than four pounds in weight. The higher orders occasionally use also beef and mutton boiled to rags, with the addition of a little pillau. The cawa, made from the husk of the coffee-berry, is drunk by most of them several times a-day, and the pipe is rarely out of the hands of the men. They are not very strict in the ceremonies of their religion, except in the performance of their ablutions, and on the Friday, the Mahometan Sabbath, the lower orders carry on their usual occupations. Since the triumphs of the British arms in India, their conduct has become more tolerant towards Christians, who may now walk along the streets without being liable to insult, but who are still prohibited from going out at the Mecca-gate, though both Jews and Banians are indulged with that privilege. The character of the Arabs who inhabit the town is very inferior to those of the country, who still follow the pastoral habits. They are cowardly, cruel, revengeful, lewd, dishonest, inordinately addicted to falsehood in every form, and scarcely possessed of a single good quality. See Parson's *Travels;* Valentia's

Voyages and Travels, vol. ii.; Bruce's *Travels*, vol. ii. (*q.*)

MODENA, (*Mutina*,) a city of Italy, situated in North Latitude 44° 38′ 51″; and East Longitude, reckoned from the meridian of Ferro, 28° 34′ 59″.

This city is situated on the *Via Emilia*, in the pleasant plain of Lombardy, and is the capital of the duchy of Modena. It is also the seat of the sovereigns, and of the supreme tribunals. It is surrounded by a good wall, with a fortress in the side between the north and west, and is distinguished by spacious squares and streets, adorned with noble edifices, pleasant environs, and by the ample public promenade, which was formed and embellished by the present sovereign, Francis IV. The royal palace is one of the finest in Italy. The tower is of beautiful architecture, all coated over with white marble, one of the seven of that description in Italy. It is a singular property of the Modenese soil, that in digging into the earth, to the depth of about sixty feet, there arise veins of very pure spring-water; thus affording excellent perennial fountains. The population of this city amounts to about 26,000 souls.

Modena is a very ancient city, of which the first mention occurs in the year of Rome 535, during the war with Carthage: at which period the triumvirate commissioned to assign the lands to the new colonists shut themselves up in Modena, in order to escape the fury of the Baic Gauls; from which circumstance it may be inferred, that this city was, at that time, well fortified, and capable of enduring a siege; and, therefore, most probably founded a long time before. In the year 567 it was made a Roman colony; and, in the civil war which broke out in the year 675, between the two consuls Q. Catulus and M. Lepidus, Pompey here besieged M. Brutus, father of that Brutus who killed Cæsar. Still more celebrated was the siege sustained here by Brutus, in the year of Rome 709, against M. Anthony, and the defeat of the latter in the year 710, under the walls of the city, by the consuls Hirtius and Pansa, with Cæsar Octavianus, afterwards Augustus, in consequence of which Anthony was compelled to raise the siege. Seven months after this victory, Lepidus, Octavianus, and Anthony, divided the republic among them into three parts, having met for this purpose in a small island in the river Lavino, in the Modenese territory, according to the opinion of most writers. The revolutions to which Italy was exposed during the time of Constantine, and the invasions of the barbarians, were more or less common to the city of Modena, which, after having figured at the time of the peace of Constance among the Italian republics, and being in danger from the internal factions of the Guelfs and the Ghibbellines, threw itself into the arms of the Princes of Este, by electing for its sovereign, on the 15th December, 1288, Obizzo II. Marquis of Este. These princes governed the city until towards the commencement of the fourteenth century, when the desire for republican forms again revived in Italy. From this period there was an *interregnum* of about forty years, during which Modena was governed by various masters, and suffered much from hostile factions. Finally, in the year 1336, Obizzo III. of Este, resumed possession of the city, which his successors enjoyed till the year 1796, with the exception of some periods of interruption, occasioned by the wars which from time to time desolated the Italian peninsula. In the last mentioned year Modena was occupied by the French, and afterwards formed a part of the kingdom of Italy, until the year 1814, when it was restored to its legitimate sovereign, Francis IV. Archduke of Austria.

The government is monarchical. There is, however, a noble regency of conservators, who administer the public patrimony of the community, under the direction of a governor named by the sovereign. There is a bishop, a chapter, and a seminary; and also a flourishing college for the education of native and foreign nobles. The university has been restored by the reigning sovereign, who allows the students the use of his vast and elegant library, which is preserved in his royal palace, and is rich in books and precious manuscripts. He has also revived the Academy of Sciences, literature, and the arts, the Academy called Atestina, or the fine arts, and has here fixed the seat of the Italian Society of Sciences, formerly instituted by the illustrious Chevalier Gio. Mario Lorgna Veronese. The Capitular archive of the cathedral is celebrated on account of the antiquity of its documents, and its very honourable, royal, and imperial diplomas, among which are some originals of Charlemagne. Still more rich is the secret archive of the family of Este, in which are preserved a great many precious parchments and remarkable documents relative to the antiquity and grandeur of that family, one of the most ancient and noble lines of sovereign princes. There are various charitable institutions in Modena, among which are the grand hospital, the house of recovery, and the house called St. Paul, which was recently founded by the present sovereign for the education of poor girls.

Many learned men have flourished in the dominions of the house of Este, as may be seen in the work, entitled *Biblioteca Modenese*, by C. Tiraboschi; and among whom are distinguished the names of Sigonio, Castelvetro, Montecuccoli, Vallisniere, and Muratori. The means which this city possesses at present for the cultivation of science, literature, and the arts, have brought letters into high estimation, and rendered flourishing the study of the sciences.

The country, in general, is fertile in all kinds of grain, leguminous vegetables, and mulberries; and in all sorts of large and small cattle, grapes, chesnuts, and fruits. The principal commerce of this state consists in wines, spirits, silks, bestial and coarse cloths. Few manufactured articles are exported; because, being an agricultural country, the greater part of its population is employed in cultivating the ground. It has, however, one very lucrative branch of commerce, viz. that of hats, called *cappelli di truicolo*, of which great numbers are exported.

MOFFAT, the name of a town and parish of Scotland, in the county of Dumfries. The town is situated on the east side of the river Annan, at the head of a plain or valley extending upwards of 20 miles along the banks of the river.

The principal street, through which passes the great road from Edinburgh to Dumfries and Carlisle, is spacious. The town contains many good houses, two inns, excellent lodging-houses, with a handsome church, and an assembly-room.

Moffat is principally celebrated for its mineral waters. The sulphureous spring called Moffat Well is situated about a mile and a half from the town. There is a good carriage road to the well, and excellent accommodation for the company while they are drinking the water. This well was discovered about 170 years ago; and, according to Dr. Garnet, it contains muriate of soda, 36 grains, sulphuretted hydrogen gas, 10 cubic inches, azotic gas, 4 cubic inches, and carbonic acid gas, 5 cubic inches.

The chalybeate spring called Hartfell Spa, issues from a rock of alum slate, on a tremendous ravine on the side of Hartfell. According to Dr. Garnet, a wine-gallon of it contains sulphate of iron, 84 grains, sulphate of alumine, 12 grains, azotic gas, 5 cubic inches, together with 15 grains of oxide of iron, with which the sulphuric acid seems to be supersaturated, and which it gradually deposits on exposure to the air, and almost immediately when boiled. The other chalybeate spring near the bridge is now choaked up. There are vestiges of a Roman military road, and of several stations near the town. About a mile east of the Roman road are two large caves cut out of freestone rock.

In 1811, the parish contained 406 families, of whom 120 were employed in trade, and 72 in agriculture; and the total population was 1824 inhabitants. See Dr. Singer's *Agricult. Account of Dumfries-shire*, p. 48, &c.

MOGADORE, or Mogodor, a maritime town of the empire of Morocco, is situated in 29° 50′ of north latitude, and 9° 36′ of west longitude, about 48 miles south of the river Tensift. It was founded in the year 1760 by the Emperor Mohammed-ben-Abdallah-ben-Ismael, and received its name from a sanctuary in the vicinity called Seedi Mogodol. But by the Moors it is called Suerah, or more properly Saweera, a name conferred upon it by the Emperor in allusion to the beauty of its appearance, and particularly the regularity of its construction. It is built upon a low, flat, sandy tract, and in spring tides is almost surrounded by the sea, but is defended from the encroachment of the ocean by a line of rocks, which extend from the northern to the southern gate. The harbour, or bay, is formed by a curve in the land, and a small island, about a quarter of a mile from the shore, but is rather shallow, and daily becoming more so, by the accumulation of the sand, so that ships of war, or of great burden, must lie at anchor above a mile and a half west of the Long Battery on the west of the town towards the sea. At the entrance of the road is a circular battery, and, within the harbour, at the landing place, are two long batteries mounted with handsome brass eighteen-pounders. On the land-side also, to the eastward of the town, is a battery of considerable force, fully sufficient to keep the Arabs at a distance; and were the other forts well mounted and manned, it is supposed that six or seven large frigates would be required to reduce the place. There is a very spacious cistern under the battery at the Water-port gate, which is filled with rain-water from the adjoining terraces, which is never used except in cases of emergency; and as the water for the use of the town is brought from the river, this supply might be rendered inaccessible in the event of an attack. There are two towns, or rather a citadel and an outer town, both of which are walled in and protected by cannon. The citadel contains the custom-house, the treasury, the residence of the alkaid, the houses of the foreign merchants, and those of some of the civil officers; and as the houses are all of stone, and of a white colour, the appearance of the town at a distance is extremely beautiful; but the streets (which cross each other at right angles) are very narrow, and the houses have few windows towards them, so that the interior of the place has a sombre look. The houses of the foreign merchants are very spacious, having eight or twelve rooms on a floor, all opening into a gallery, which goes round the whole inside, forming an area in the centre which is appropriated to the transacting of business and the warehousing of goods. The roofs are flat, and beat down with a composition of lime and small stones, which forms a very durable covering, and serves as a walk for the family.

The emperor who founded the town was very desirous to render it a flourishing commercial port. To impress his wishes on the minds of the inhabitants, he commanded his principal officers to bring mortar and stones, and with his own hands he began to build a wall, which is still to be seen on the rocks to the westward of the town. In order also to encourage the merchants to erect substantial houses, he not only presented them with ground, but allowed them to ship produce free of duty, as a remuneration for their expenses.

The Arabs, however, have so great a repugnance to quit their tents, and such a contempt for the restraints of a town residence, that he was obliged to draft a certain number of persons from the Arab or Bezebber tribes, as well as from some of the towns, and to compel them to settle in his new city. The population now amounts to about 10,000, and it is the only part of West Barbary which maintains a regular commercial intercourse with Europe. It differs from every other port along that coast in this respect, that the inhabitants have no other resource or occupation than commerce, and by it every individual is directly or indirectly supported. The town is in a manner insulated by sand-hills, which separate it from the cultivated country, and which are so continually drifting by the incessant high winds of summer, that scarcely any kind of esculent plants can be raised for the supply of the inhabitants. The fruits and vegetables are therefore brought from gardens between four and twelve miles distant; and the cattle and poultry from the other side of the sand-hills. The foreign merchants of Mogadore supply the various cities and markets of the empire with European goods, receiving in return the produce of the country for exportation; and formerly used to give to the natives credit to a considerable extent. But of late years the Moorish government has greatly abridged their power of enforcing payment, so that credit is almost annihilated, and transformed into barter, which has curtailed the trade, and confined it among fewer hands. The principal imports are Yorkshire and West country cloths of various colours, superfine cloths, druggets, linens, cambrics, muslins, Indian blue linens, striped India silk, velvets, damask, and raw silk, alum, copperas, sugar, iron, hardware, gums, spices, tea, pewter, tin bars and plates, white and red lead, copper in sheets, thread, mirrors, earthenware, glass, brass pans and copper teakettles, Dutch knives, paper, cotton, coral and amber beads, wire, cochineal, iron nails, deals, dollars; which, with several other articles, amounted in 1804 to the value of 151,450*l*. The principal exports are almonds, walnuts, gums, wax, hides, olive oil, wool, ostrich-feathers, elephant's teeth, dates, raisins, anise-seeds, tallow, &c. which amounted in the same year, after paying freight and duties, to 127,679*l*. The police of the town is very strict, and there is neither house-breaking nor rioting in the place. The governor of the city frequently goes the rounds in person, and looks the watchmen in the face, who lie on their sides with their ear to the ground, that they may the better hear any noise, and who would be in danger of capital punishment, if found asleep on their post. See *Jackson's Account of Morocco;* Chenier's *Present*

State of the Empire of Morocco; and Paddock's *Narrative of the Shipwreck of the Oswego.* (*q.*)

MOGUL EMPIRE. See India.

MOHAWK, a river of the United States, in the state of New-York, is the north-west branch of the Hudson. The Mohawk rises in Lewis county, by a number of branches, which unite, and flow south to Rome, in Oneida county. Here this river turns to a little south of east, which course it pursues to its junction with the Hudson at Waterford and Lansingburgh. The Mohawk is impeded by two falls; these are, the Little Falls, in Herkimer, and those of Cohoes, between Saratoga and Albany, two miles above Waterford.

The entire length of the Mohawk, by comparative courses, is about 130 miles; it is navigable at high water below Rome. This stream receives from the north only two creeks of any consequence, East and West Canada, and from the south Schoharie river, from which the county of Schoharie takes its name.

Darby.

MOISTURE. See Hygrometry and Meteorology.

MOLD, a town of Wales in Huntingdonshire, is agreeably situated on the river Alum. It consists of four streets, which are neat and wide. The houses are in general well built. The principal public buildings are the church, the town-hall, in which the assizes are held, and a large hospital. Great quantities of coarse woollen cloth were formerly manufactured here; but the inhabitants are now employed principally in the manufacture of copper and brass articles, and the knitting of stockings. The remains of its ancient castle, and some ruins, supposed to be Roman, are the only antiquities of the place. The town contains 700 houses, and 4235 inhabitants. See the *Beauties of England and Wales*, vol. xvii. p. 689, and Wynne's *History of Wales.*

MOLDAVIA, a country of Europe, bounded on the north and north-east by Poland and the river Dneister; on the south by Bessarabia and the Danube; and on the west by Wallachia, Transylvania, and branches detached from the Carpathian mountains. Its extreme length is computed at 280 miles, and its breadth at 200. The surface is finely diversified with hills and valleys, with extensive forests and numerous streams, of which the principal are the Pruth, Sireth, Moldau, Danube, and Dneister; and it contains several small lakes. But the summer heats convert several of the latter to marshes, exhaling dangerous miasmata. The climate is rigorous in winter, and oppressive in summer. During six weeks the Danube is frozen; when the ice is capable of bearing the heaviest artillery, and the intercourse on land is by means of sledges on the snow. Much rain falls in summer, accompanied by thunder storms every evening about the same hour, and slight earthquakes are frequent.

Moldavia abounds in minerals. Particles of gold are rolled down by some of the rivers. Fossil salt is plentiful; a quantity of nitre is exported; and the prince of this territory must send 25 tons of nitre yearly to Constantinople.

The Turkish navy is supplied with the finest oak from the forests of Moldavia, and also with masts and cordage of native growth. Wheat, barley, oats, millet, and maize, are in ordinary cultivation; the usual return is sixteen fold, and in favourable seasons twenty-five. Vines are planted in sheltered situations on the declivities of hills, but the grapes are not allowed to come to perfection, whence the wine obtained from them is inferior, though a great quantity is exported.

Great numbers of bees are reared by the Moldavians. The hives are lodged in portions of the hollowed trunk of a tree, about three feet long, and closed at the upper end. Those converted to use are smoked towards the end of October, and those meant to be preserved are kept in cellars covered with straw during winter. Bees are an article of taxation: The produce of the tax, in 1785, amounted to 4000*l.*

The principal domestic animals are horses, cattle, sheep, and goats; and great herds of swine are fed in the forests; the wild animals are wolves, foxes, bears, martins, hares, and others. About 10,000 martins are taken yearly, and about 500,000 hares, in this country and Wallachia, which are chiefly hunted during winter. It was lately computed that the principality contains 3,248,000 sheep and goats; a large proportion of which are carried to Constantinople; for the Turkish government sends a company hither every spring to purchase domestic animals and provisions, in an oppressive manner, at a low and arbitrary price. The horses are esteemed for their spirit and docility, and are bought for the use of the Austrian and Prussian cavalry. Some of the wealthy proprietors have 400 or 500; and it is said they allow them to remain always unsheltered in every season. Beyond the river Pruth there is a particular breed, superior to the rest.

The government is nearly absolute, in the person of a prince, waivode or hospodar, appointed by the Turkish emperor, and selected from the Greek families at Constantinople. He purchases his appointment, and its duration is dependent on the Turkish government. A divan, or supreme council, consisting of twelve members, assembles at least twice weekly to decide on judicial and other matters; but its authority is rather nominal than real, almost every thing being conducted at the pleasure of the prince. The laws of the province have been lately revised and published, by command of the present prince of Moldavia, who was appointed in the year 1812. Capital punishment is very rarely inflicted; but the prince has absolute power of life and death throughout his government.

The prince of Moldavia is responsible to the Porte for a yearly tribute of a million of piastres, or 33,333*l.* sterling; and the total revenue of the country is said to amount to 46,666*l.* The sources of revenue are a capitation-tax from the peasantry, and small landholders, salt mines, customs; a tax on tobacco, wine, bees, and the pasturage of sheep and cattle.

The chief trade of Moldavia consists in the export of timber, grain, yellow berries, live stock, wool, wine, wax, and honey; and in the import of coffee, sugar, pepper, rum, fruit, foreign wines, furs, cotton and woollen cloths, glass and earthen ware. Timber for ship-building and staves is floated down the smaller rivers into the Danube; wheat is contraband, but Turkish vessels come to carry away about 1,500,000 bushels from this and the neighbouring principality, by the authority of government. Wax is carried to Venice, and honey to Constantinople: and the other articles, most of them loaded with improvident restrictions, are exported elsewhere. About 1120 tons of coffee, and 1260 of sugar, are imported at Galatz yearly; and manufactures of different kinds from Germany, which are offered as English, meet a ready sale. The fur and leather trade is mostly conducted by Russians, the silk and woollen by Greeks, the morocco-leather, spiceries, and aromatics, by Turks, and jewellery by Jews.

The total population of Moldavia was computed in 1794 at 420 500 souls, of whom 20.000 were supposed to be ecclesiastics. At present the population is calculated at 500,000. The greater part is dispersed in the country, inhabiting miserable villages, where the huts are fashioned of wood, daubed with clay, having doors that scarcely close, paper windows, and the roof open to the winds. In winter their tenants descend to subterraneous cells, which are easily heated, where both sexes and all ages mingle promiscuously together, sleeping on a coarse rug, which serves them equally for bed and coverlet. They subsist for the most part on a kind of thick porridge or dough, called mamalinga, made of the flour of Indian corn. During a famine in 1795, they were compelled to live on acorns and the bark of the elm, ground and mixed with meal; yet many, deprived of even this wretched fare, died of want.

There are few towns of considerable size or importance. The capital, Jassy or Yassi, is situated on the lake and river Baklui, running into the Pruth, and occupies a vast extent of ground, from the houses being detached, and surrounded by yards and gardens. The cathedral, churches, and convents, the palaces of the boyars, or nobles, and that of the prince, form the most conspicuous features. The last is very spacious, fitted up partly in the European style, and is capable of accommodating 1000 persons. In general the houses consist of only one storey, built of brick, and whitewashed both without and within, and are roofed with wood; but there are many of a different construction, and after the best style of European architecture. Yassi contains seventy churches, public hospitals and schools for about 200 pupils, who are instructed in the national language, ancient and modern Greek, writing, and arithmetic. Education nevertheless is very much neglected throughout the principality. Many coachmakers are established here, from the custom among the better classes of never going out on foot. The streets, instead of being causewayed, are floored with thick beams of the finest oak, which must be renewed every five or six years. In rainy seasons they are covered with deep liquid mud, and in dry weather with thick black dust, which, added to the stagnation and accumulation of putrescent substances below, are productive of numerous diseases. Hence Yassi is esteemed an unhealthy residence, and the inhabitants are constantly afflicted with intermittent, bilious, and putrid fevers. Its population is computed at 40,000. Galatz, the sea port and chief emporium of the province, is situated on the Danube, 65 miles from Yassi, where that river is navigable by vessels of 300 tons burden. Here there are public granaries for wheat, and many large warehouses belonging to private merchants. A number of vessels frequent the harbour, among which are some from the Ionian islands, of late under British colours. The stationary population of this town amounts to 7000, but there is a great resort of strangers engaged in commercial pursuits.

Moldavia is part of the ancient Dacia, whose inhabitants resisted the progress of the Roman arms. The King of the Visigoths, being compelled to retreat hither in the fourth century, erected a wall between the Pruth and the Danube, where various antiquities of a remote era, as described by Count Marsili and other authors, are still to be recognised. In the thirteenth century it was occupied by a new tribe, under their leader Bogdan, who assumed the Sclavonic title, wayvod or voivode, equivalent to reigning prince, and from him the country received the name, Bogdiana. It became tributary to Turkey in 1536, and since, having been the theatre of sanguinary wars between that empire, Russia, and Austria, each has alternately held the sovereignty. At length the growing power of Russia obtained the cession of the best portion of the province, between the Pruth and Dneister, in the year 1812, which may perhaps be anticipated the precursor of the rest, on the commencement of the first hostilities between the empires.

MOLIERE, (Jean Baptiste Poquelin,) the most celebrated author of French comedy, was born at Paris in 1620. His father and granfather were valet-de-chambre upholsterers to the royal household of France. Young Poquelin remained in his father's house till the age of fourteen, receiving no other education than was conformable to the employment which it was intended that he should follow; but having acquired a taste for reading, he was, by his own earnest desire, and at the instance of his grandfather, sent as a day-scholar to the Jesuits' College of Clermont. He there formed an intimacy with Chapelle, Bernier, and some other men of promising talents, and through their friendship was permitted, in their company, to attend the lectures of the celebrated Gassendi. The journey which Louis XIII. made to Narbonne, in 1641, gave a temporary interruption to the course of his studies; for his father having become infirm, and unable to follow the court, young Poquelin was obliged to go in his place, and to attend to the duties of his father's office; but on the death of his father, he returned to Paris, and had it in his power once more to pursue the bent of his genius. It luckily took a turn for the theatre. The taste for theatrical entertainments was, at this time, at a great height in France. Cardinal Richlieu himself was attached to them, and protected dramatic authors.— Among the new companies of comedians which began to be formed at Paris, our author entered into one of them, which was called L'Illustre Theatre. It was at first only a private society, established for the sake of amusement; but by degrees it made its exhibitions public, and fixed itself in the suburbs of St. Germain's. Either from regard to the feelings of his relations, who disapproved of his following this vocation, or after the example of his comrades on the stage, our author dropt his proper family name of Poquelin, and assumed that of Moliere, by which he was destined to be known to posterity. He soon after associated himself with a provincial actress, called La Bezart, and they formed a company, which set out for Lyons. At that city, in 1653, his comedy "*L'Etourdi*" was for the first time represented. Being an early essay, this piece (as we might expect) is not to be ranked among the masterpieces of Moliere. It has more intrigue than interesting delineation of character; and the events do not spring out of each other with that felicity and force of natural succession, which he afterwards so well knew how to infuse into his comic plots; but it has great vivacity of dialogue, and contains one character, the intriguing valet Mascarille, which is highly amusing. If we consider, too, the state of French comedy previous to Moliere, which was nothing better than a compounded imitation of the extravagance of the Spanish, and the buffoonery of the Italian drama, the appearance of the "*Etourdi*" must be regarded as an era in the national literature. This comedy went off at Lyons with great eclat, and Moliere proceeded from thence to Languedoc, in order to offer his services to the Prince of Conti, who at this time presided over the states that were assembled at Beziers. Here Armand de Bourbon, who had known our author at Paris, and had often been amused with his acting in the "Illustre Theatre," received him with great kindness. The "*Etourdi*" was reacted at Beziers with the same success as at Lyons, and was quickly followed by "Le Depit Amoureux," and "Les Precieuses Ridicules." The former of those pieces displays Moliere as a poet, still relying mainly for comic effect on the intrigue and surprise of incident which prevail in the Spanish school; though there is a more artful arrangement of incidents than in the "*Etourdi*," and great pleasantry and ingenuity displayed in the labyrinth of perplexed situations in which the characters are involved, and from which the denouement dismisses them. The latter piece, the "*Precieuses Ridicules*," is of a higher order of comedy. The author shines here, for the first time, as a deep and delicate painter of manners and characters. It is an exquisite satire on the affectation of high-flown sentiments and witty language, which are said to have then prevailed in France. The piece was acted incessantly for four months, and the confluence of spectators enabled the managers to charge double price for admission to see it. Among the compliments paid to it, one is mentioned to have been uttered by an old man, who cried out from the gallery, "*Courage, Moliere! voila une vraie comedie!*" His reputation was now widely established; and he had a right to congratulate himself on the profession which he had chosen. But all his success and celebrity could not overcome the repugnance of his relations to seeing him on the stage, and he was repeatedly besought by them to forsake it. Believing that the master of a boarding-school, with whom he had once lived, might have some influence with him, they sent the grave man to try to persuade him to give up the life of a player; but the result of the embassy was worthy of the history of a comic actor and comic author. Instead of being converted by his friend the schoolmaster, he persuaded the elderly gentleman to become himself a player, and launched him on the boards in the character of a comic doctor, which he thought suited his appearance.* He next visited Grenoble and Rouen, and from the latter place returned to Paris, under the protection of Gaston Duke of Orleans, who introduced him to Louis XIV. and the Queen. He obtained permission to open a theatre in the metropolis; and the Guard in the old Louvre was first allotted him for that purpose. In 1664. it was changed for that in the Palais Royal, and, in 1665, he was placed in the service of the King, with a pension. He continually fed his reputation with new works, and produced many farces and slight pieces, besides his regular comedies. In 15 years he supplied the theatre with thirty productions. Though his fame, however, was on the whole progressive, he was neither exempted from invidious nor just criticism; nor were all his pieces equally well received. From his comedy "*Le Cocu Imaginaire*," it was supposed that his style improved after his establishment in Paris; but his "*Don Garcia de Navarre*" acquired no reputation, and he yielded to the public opinion by forbearing to print it. In his subsequent piece, "L'Ecole des Maris," he however indemnified himself for this temporary failure. Among the principal objects of his satire, were the coxcomb men of quality of his time, called the petits-maitres, the pedants, and the affected belles esprits, male and female, and the medical faculty. His L'Amour Medecin was the first piece in which he embarked in a war with the last of these tribes, which continued all his life; for the "*Malade Imaginaire*," in which he still holds up the faculty to ridicule, was the concluding work of his life. The influence of common sense on modern manners has, no doubt, stript every description of professional men of any peculiarities which formerly belonged to them, so that Moliere's picture of doctors in the 17th century is likely to appear to us more exaggerated and illiberal than it really was with regard to the originals: nor is it assuming too much to suppose, that the very ridicule of Moliere contributed to diminish those traits of charlatanism and pedantry, which it would be, at this day, the lowest resource of caricature and farce to ascribe to the medical character. His comedy of the "Misantrope" is placed by his admirers in French criticism very high in the scale of his works, perhaps it is generally regarded as inferior only to Tartuffe. It is sadly defective, however, in interesting action, and has a great deal of prosing discussion in the dialogue, meant to pourtray characters by the repeated expression of their opinions and principles. In this respect he sometimes reminds us of our own Ben Jonson, and his imitators Cartwright and Randolph, in their less happy moments, when they substitute hard and abstracted ideas of human character for its natural development, and for the amusing business of comedy. The "*Misantrope*" was, accordingly, too spiritual in its touches for the Parisian audiences, and it was not so kindly received as his pieces of broader humour. In recompense, it has since received the suffrages of the more philosophical class of French critics, and it has unquestionably some fine traits of character-painting, amidst the superabundance of its opinionative discussion. One philosopher, J. J. Rousseau, has, with his accustomed singularity, objected to it on the grounds of its moral tendency. "It is a piece (he says) which holds virtue up to ridicule. This paradox was worthy of the writer who would have sent back human nature to barbarism as to a golden age. The misanthrope Alceste, Moliere's hero, he observes, is a man of rectitude, sincerity, and genuine worth; and yet he is made to appear ridiculous." All this is sophistry. Alceste, it is true, is represented as an honest man, whose "*failings lean to virtue's side;*" but still, with all his worth, he has failings, and they are legitimate objects of ridicule. The misanthrope's love of truth and plain dealing is carried, as Rousseau's sometimes were, to spleen and rudeness; as, for instance, when he has the cruelty to tell a poor vain poet to his face, that his

* We quote this anecdote from *Les Annales Dramatiques*, published at Paris in 1810.

verses are execrable. His positiveness in maintaining this point is made entertainingly extravagant, when, on being told that he is to be taken before a court of the marshals of France, he offers to prove that any man deserves to be hanged for making such verses. Here the virtue of sincerity is not, as Rosseau alleges, held up to derision; but the misdirection of the virtue. We are not made to laugh at the misanthrope's love of truth—but at his putting himself into a passion about a trifle, which neither called for his sincerity, nor justified his ill temper. The scene is therefore neither immoral nor irrational. But still Rousseau will insist that Moliere has degraded the picture of a good man, at the expense of consistency of character. He ought, he says, to have made him furious only against public vices, and not against the personal traits of wickedness of which he is the victim. The plain answer to this is, that it is most natural for a man to feel indignant at the vices which immediately affect his own happiness. Moliere certainly might have made his hero a *public-spirited misanthrope;* but unfortunately there are so few men-haters of this description, who are believed to be sincerely abstracted from all considerations of their own interest, that a misanthrope insensible to personal injuries would not have been, probably, received as a very natural character. He might have made him, if he had liked, a perfect and a wise being; but where would have been then the scope for comedy? Where would have been the failings to instruct us? And if he meant to paint a misanthrope, with what consistency could he exhibit a wise and perfect being? Such a man, if he existed, would not hate his species, but regard their errors with the very soul of compassion.

His "*Tartuffe*" is esteemed by his countrymen as the masterpiece of his works, and of their national drama. We must own that, to our taste, some others of his comedies, such as "*Le Bourgeois Gentilhomme*," "L'Ecole des Femme," &c. and "Le Malade Imaginaire," which bring "*laughter shaking both her sides*," seem to possess a more veritable tone of humour than the exhibition of so dark a villain as Tartuffe. We are not deterred from avowing this preference by the common remark, that the first and last of these pieces, in particular, incline to broad farce, and give us rather caricatures of transient follies in the manners of society, than draughts of permanent resemblance to human nature. But though the ludicrous images in these comedies may be bold and broad, we are not aware that they are unnatural; on the contrary, though they are heightened sketches of follies, which never meet us so glaringly in real society, we believe they seize the veritable, essential, and permanent traits of the ridiculous in human character. The absurdities and frailties of the species may be thus shewn, like playful or pernicious insects through a magnifying glass, but their stings and gambols and propensities are, by that means, only shewn to us more distinctly. With respect to the Tartuffe, the fault of its conclusion, by a resource supposed illegitimate in the drama, has been a thousand times noticed, namely, the order from supreme authority, which arrests the villain when he is at the height of his triumph, and conducts him to a terrible punishment. The gravity of the scene, we confess, seems to us a greater departure from comic effect than the means employed for the denouement; and in what we have said of the Tartuffe, we only mean that it is less exhilarating than the other comedies which have been mentioned. As an effort of skill and ingenuity, it is wonderful, for the art with which he throws a risible interest over the exhibition of such dark traits of atrocity as those of Tartuffe, and with which he amuses us by the success of a knave, all the time we are impatient for his detection. The subject was difficult, but Moliere had to encounter other difficulties than those of his subject. His exposure of the vice of hypocrisy in Tartuffe alarmed not only hypocrites, but some of the weak and well meaning devout. Whether we are to reckon Louis XIV., and his immediate advisers on this point, among the real or pretended devotees, it is certain that his Majesty, for some time, laid his veto on the representation of the comedy. The three first acts of Tartuffe had been represented, after the fetes of Versailles, in 1664, in presence of the King and the Queen-mother and consort. Louis declared, that, for his own part, he had nothing to say against the comedy; but he forbade its being represented in public, till it should be examined by persons capable of estimating its moral tendency. The bigots availed themselves of this circumstance to raise a clamour against the piece; though, for the most part, they were little acquainted with its contents. A pious curate, in a book which he presented to the king, decided that the author deserved to be burnt alive, and upon his own private authority awarded that punishment to Moliere. Some of the higher clergy, however, having had the moderation to hear the comedy read, were pleased to judge of it more charitably. A verbal permission for its representation was obtained from the king. The poet softened some expressions, which had appeared offensive; he gave it the title of "L'Imposteur," and disguised the person of his hypocrite under the appearance of a man of fashion, giving him a small hat, bushy locks, a sword, and a laced suit of clothes. In this state Tartuffe was risked on the stage in 1667, and was received with applauses; but next day an order was sent to suspend its representation; and though, at Moliere's instance, two gentlemen, "La Thorilliere," and "La Grange," repaired to the camp before Lille, where the King then was, and presented a memorial in favour of the piece, it was not till two years later that his Majesty gave an authentic permission for its being again brought on the stage. When it became fully known, the hypocrites were confounded, and the poet was justified, with regard to the dangers to the cause of morality which were supposed to be apprehended from the play of Tartuffe. We omit to give the particular dates or names of his numerous pieces. "La Malade Imaginaire" was the last of his compositions. The day on which it was to be represented for the third time, he felt himself more indisposed than usual with a complaint in his chest, to which he had been subject for a long time, and which had brought on an almost incessant cough. He makes an allusion to this infirmity, which must have often interfered with his acting, when Frosine says in "the Avare" to Harpagon, a part which Moliere played, "Cela n'est rien, votre fluxion ne vous sied point mal, et vous avez grace a toupir." (L'Avare, act 2, scene 6) His wife and friends intreated him to defer the representation of "Le Malade Imaginaire" till his health should be somewhat reinstated; but he answered, "What then must become of so many poor people, who depend upon its representation for their bread? I should reproach myself for having neglected a single day to have supplied them with necessaries." He accordingly exerted himself on the stage with unusual spirit, in performing this comedy; but in the third act he was seized with a convulsion fit, which he vainly attempted to disguise to the spectators by a forced laugh. He was carried home to his house in the Rue de Richelieu, where his cough augmented exceedingly, and brought on a vomiting of blood, that ended in suffocation. He expired on the 17th February, 1673, aged 53—supported by two women of the religious sisterhood, who used to come to Paris in time of Lent, for the purposes of charity. Harlai, the Archbishop of Paris, a man of dissolute morals, but desirous of pleasing the rigorists of the Roman church, refused him Christian burial; but the King interposed, and the prelate, after pretending to investigate the character of Moliere, and to be satisfied with the accounts which he received of his religion and probity, allowed that he should be interred privately in a chapel of the parish of St. Eustache. Another story is told, of the King having sent for the curate of the same parish, who, like his superior, had scruples about the right of a player to be buried in consecrated earth. "To what depth is your ground consecrated?" the King is said to have inquired. "To the depth of four feet," answered the clergyman. "Well then," replied Louis, "let Moliere be buried six feet deep;" and he added, as he turned his back upon the curé, "let me hear no more about this business." The bigotry of the populace impeded even the obscure funeral honours which were allowed to be paid to him, for they collected in great crowds before the door of his house on the day on which his corpse was brought out. Such was the return which his country made to the man whom Racine himself pronounced to be the greatest of his age. His wife, on hearing the refusal of the clergy to allow him Christian burial, is said to have exclaimed with tears in her eyes, "*France grudges a tomb to him to whom Greece would have erected altars!*" The saying was just and pathetic. It is only to be regretted, that the wife who spoke it was not, if we may trust the general report, worthy of Moliere. He is said to have been himself the victim of the most grievous of matrimonial distresses, which he paints so facetiously in comedy. The populace, whom his widow bribed to respect his remains, followed him decently to his grave; where he was quietly deposited by the light of an hundred flambeaus, which his friends carried to the ceremony. His widow afterwards married a comedian of the name of Guerin. She was the daughter of Madame Bezart, with whom he made his first theatrical excursion to Lyons, and with whom, it seems to be confessed by his biographers, that he had had a connexion before he was married to the daughter. The exasperated envy of some of his literary opponents accused him of espousing his own daughter in this Mademoiselle Bezart; but the calumny is sufficiently refuted by distinct evidence, that she was born before Moliere became acquainted with her mother. Moliere was in his person above the middle size, of a noble carriage, handsome limbs, and an exceedingly expressive countenance. His walk was slow—his air serious.—He had a high nose, a large mouth, a dark complexion, and very black, thick, and flexible eye-brows, which made his physiognomy very striking in comedy. He was not, probably, a first rate performer, owing to the weakness of his voice; but from the prominent parts which he took in his own comedies, he must have been a considerable one, and by no means incapable of doing justice to the characters which his imagination so strongly conceived. We are told by the French actress, who gives this minute description of his appearance, that he was fond of talking (*il aimoit fort a haranguer*) and that, when he read his pieces to his fellow-actors, he always wished them to bring their children, in order that he might draw hints from their natural movements. The same person adds, that he was mild, courteous, and kind in his general intercourse. He was not envious: to be sure he had little occasion to be so. When the "*Plaideurs*," a comedy by Racine, with whom he was at that time on bad terms, had lost possession of the stage, he was the first to assert its merit, and to bring it back to popularity. In company that pleased him, his conversation was very pleasant; but, as the contrary oftener happened, he was apt to be absent and melancholic in society, and consoled himself with secretly remarking the traits and manners of those about him, in order to store them up as hints for comedy. Many anecdotes of his benevolence are recorded. His friend Baron one day mentioned to him the case of a man whom extreme poverty prevented from waiting on him. His name was Mondorge.—"I know him," said Moliere. "He was a comrade of mine in Languedoc, and an honest man. How much do you think I should give him?" "Four pistoles," said Baron, after some hesitation. "Here, then," replied Moliere, "are four pistoles for me, and here are twenty more, which you shall give him from yourself." Mondorge was introduced to him: Moliere received him with open arms, and gave him also a magnificent dress, which enabled him to perform a tragedy. A beggar once asked our poet for charity, and he gave him a piece of gold. The mendicant brought it back, saying he supposed it was a mistake. "In what a hole has virtue hid herself!" exclaimed Moliere, and gave another gold piece to the poor man, telling him there was no mistake. His death, as we have seen, was occasioned by an impulse of benevolence. A high niche in the temple of modern genius is confessedly to be assigned to this writer, but whether he is to be ranked among the few first rate comic poets who bear the palm in universal literature, ancient and modern, is a question still agitated between the schools of French and German criticism. Voltaire has named him the father of true comedy; and as far as the French stage is concerned, nobody will dispute the assertion. According to La Harpe, he is the first of philosophical moralists; comedy and Moliere are synonymous terms, and his pieces are schools of instruction for the world. Chamfort calls him the most amiable teacher of human nature since Socrates, and affirms that Julius Cæsar, who called Terence a half Menander, would have denominated Menander a half Moliere. Unhappily Julius Cæsar's opinion about Moliere is not to be collected with precision, and we know too little of Menander to institute a fair comparison. But it is easier to compare Moliere with the poets of antiquity whose subjects he has adopted; and, whatever may be the result of the comparison, it is a respectable trait in his literary character, that he had sufficient knowledge and taste to apply to classical sources for enriching his drama. He brought, indeed, to the vocation of a dramatic writer, the most eminently useful and creditable advantages. Though born in middling life, he had opportunities of studying the manners of the court. He had studied Spanish and Italian comedy, and he was able to draw from Plautus and Terence the attic salt and true tone of comic character. He possessed an inexhaustible fund of gaiety, congenial with the best models from which he drew his resources; and even those who ascribed to him scarcely more than the merit of farce and caricature in comedy, acknowledge that he designs amusing caricatures with the firmest and happiest traits. They acknowledge, for instance, that even in farcical creation, the vain-glorious soldier of Plautus is less ably pourtrayed than the Bourgeois Gentilhomme of Moliere. The German writers, and even Dacier among the French, accuse him, however, of having, for the most part, spoilt the simple comic conceptions of the ancients, by accommodating them to modern manners, and by making the plots more artificial. We must recollect, that if this was a fault in Moliere, it was not easily avoided. By simply translating the plays of Plautus and Terence, he could not have pleased a modern audience had he given his classical drama in its naked simplicity. He has borrowed the idea of his "Avare" from the Aulularia of Plautus. Instead of a simple miser, he has given us a miser in love. On this charge it has been remarked, that the morale of the piece is not improved, but spoilt, because, if an old amorous dotard should go to the theatre and see the piece represented, he might say to himself, I care little for this satire, for I am not a miser; and if a miser, who happened not to be in love, should go to see it, he might, with equal justice say, "Very true, I am fond of money; but I thank my stars, I am not in love." We perceive nothing conclusive in this argument against the propriety of Moliere doubling comic effect by the conception of an amorous miser; and if it was not an improvement on classical simplicity, it was at least an agreeable variety, acquired by departing from it. In like manner we can read his Amphytrion without diminished admiration of Plautus; but still acknowledging that Moliere has made some departures from the original of considerable skill and felicity. The same cannot certainly be said of his Fourberies de Scapin, where the Phormio of Terence is by no means altered for the better. The French seem to consider his reputation as chiefly established on his "*Ecole des Femmes*," "*Tartuffe*," "*Misantrope*," and "*Femmes Scavantes*." The two last, we conceive, have too little amusing action to rank in the very highest class of comedies. But the Tartuffe, in spite of the objection of its too grave incidents, is a master-piece of deep drawn character. The Ecole des Femmes is certainly inimitable for its comic force, rapidity of movement, and for lively and original ideas. The Bourgeois Gentilhomme may perhaps be too farcical in the last acts, when the hero gives his daughter to the son of the Grand Turk, and becomes a Mamamouchi. But Monsieur Jourdain and his wife, and the cool-blooded courtier Dormine, with the whole contents of the three first acts, form a treat for the risible faculties, which, we believe, no production of the stage ever surpassed. The court of Louis the XIV. was so deplorably dull, as not to understand the humour of the piece when it was first acted; but the king had a better taste, and told Moliere, that he had never laughed so heartily in his life. The Court was converted to his opinion, and for once we can look on the authority of Louis the XIV. without regretting that it was arbitrary. The French Academy, for some time before the death of Moliere, wished to persuade him to give up the life of a comedian, that he might become a member of their society. After his decease, they voted him a public eloge, and placed his bust in their hall, with this inscription, expressive of regret that he had not become an academician,

"*Rien ne manque à sa glorie—il manque à la notre.*"

MOLLUSCA.

The history of the great division of animals to which the term Mollusca is now exclusively confined, was investigated in a very imperfect manner by the earlier naturalists. They attended merely to the characters furnished by the external appearance, and consequently formed their systematical divisions without regard to the natural affinities of the animals—affinities which can only be traced by an examination of the structure and functions of all the organs.

The first general attempt at classification, worthy of notice, appears in the twelfth edition of the *Systema Naturæ* of Linnæus. In this work, all the animals which were considered by the ancients as Exanguineous, and termed by the more recent naturalists, Invertebral, were, with the exception of insects, included in his sixth and last class, which he denominated *Vermes*, and assigned to it the following distinguishing characters.—*Cor*, uniloculare, inauritum; *Sanie* frigida. *Spiracula* obscura. *Maxillæ* multifariæ, variæ variis. *Penes* varii hermaphroditis Androgynis. *Sensus:* Tentacula (caput nullum, vix oculi, non aures, nares.) *Tegmenta* calcarea aut nulla, nisi spinæ. Fulcra: nulli Pedes aut Pinnæ. This class of vermes was again divided into four orders—*Intestina*, animalia simplicia, absque artubus, nuda. *Mollusca*, animalia simplicia, nuda (absque testa inhabitata,) artubus instructa. *Testacea*, animalia Mollusca, simplicia, domo, sæpius calcarea, propria obtecta. *Lithophyta*, animalia Mollusca, composita. Corallium calcareum, fixum, quod inædificarunt animalia affixa. *Zoophyta* animalia composita, efflorescentia. Stirps vegetans, metamorphosi transiens inflorens animal. The second and third orders, Mollusca and Testacea, include the animals to which our attention is to be directed in this article.

This systematical arrangement of Linnæus, while it contributed greatly to enlarge the number of species, had a tendency to divert the attention from the examination of their structure. The external form was exclusively employed to furnish the distinguishing characters, and was therefore chiefly regarded by the student, in reference both to genera and species. The relation between the external appearance, and the internal structure, not having been previously determined, these characters were obviously artificial, and the unnatural combinations which resulted from their employment, displayed themselves in every genus of any extent. In the same genus animals were to be found which respire in air, associated with those which perform the same function by means of gills in water; or animals whose gills are like leaves placed externally, with those having their gills in an internal cavity. Such incongruous combinations chiefly prevail among the vermes testacea, where the shell is exclusively employed in the determination of genera and species. There is another imperfection in this system, arising from the separation of the naked and testaceous mollusca into distinct orders. There is no such line of distinction observed by nature; and very considerable difficulties occur in its practical application as an artificial arrangement. Not a few animals included in the testacea, as the Bulla aperta, have the shell so concealed under the skin, that it can only be rendered visible by the separation of the softer parts; and several animals, included among the naked mollusca, are covered, in particular places, by a corneous or shelly plate, as the Aplysiæ. In consequence of these circumstanecs, genera which are nearly related are placed in different orders, while those which possess few common properties are grouped together.

Independent of these objections, which have been made against the Linnæan classification of molluscous animals, it is still pertinaciously adhered to by many British naturalists. This influence of the *idolum theatri* is the more to be regretted, as it has retarded the progress of science, limited the field of observation, and prevented us from availing ourselves of the improvements which have resulted from the labours of our continental neighbours.

For many years the influence of the artificial method of Linnæus, in botany, had been successfully assailed in France; and the followers of the natural method at length became so numerous as to secure it a favourable reception. Various efforts were likewise made to promote its introduction into the science of zoology. This was at length triumphantly effected, in regard to molluscous animals, by M. G. Cuvier. Other enquirers, it is true, largely contributed to the accomplishment of this desirable end: three of whom, distinguished by their patient industry, deserve to be particularly enumerated, Adamson, Muller, and Poli. The former paved the way to the modern arrangements, in his *Historie Naturelle du Senegal.* Muller explored the molluscous animals of Denmark, and published the result of his observations in the *Zoologia Danica*, and his *Vermium Terrestrium et Fluviatilium Historia.* Poli, directing his attention to the structure of the animals inhabiting the multivalve and bivalve shells, published his laborious observations in his *Testacea utriusque Siciliæ eorumque Historia et Anatomie.* Many other authors might be enumerated, who have likewise contributed to extend our knowledge of the structure of molluscous animals, as Lister, Monro, and Home; but as we shall have occasion afterwards to advert to their labours, it is unnecessary to enter into further details.

The first efforts of Cuvier to illustrate this department of zoology, though necessarily imperfect, excited the attention of naturalists to the subject, and were the prelude to those mighty achievements, more recently made known to the world in his various papers inserted in the *Annales du Museum*, and republished under the title *Memoires pour servir à l'Histoire et à l'Anatomie des Mollusquès*, in one volume quarto, Paris, 1816. These papers may be considered as models of minute and accurate research, perspicuous description, and candid criticism, and merit the careful and frequent perusal of the student of molluscous animals. In the second volume of a more recent work by the same author, entitled *Le Règne Animal destribue d'apres son Organization*, Paris, 1817, he has given a synoptical view of the subject, which we intend to make the basis of the following article.

As a preliminary step to an examination of the divisions of molluscous animals, we shall take a very general view of their structure and functions, reserving the more minute details to be given under the different groups into which they have been arranged. Indeed, the several organs, as they appear in the different tribes, are so variously modified, that few common properties can be enumerated. In this section, however, we shall be able to mark the course to be observed in the illustration of the subordinate divisions, endeavouring, at the same time, to avoid saying any thing which will again require to be repeated.

1. *General Form.*—The molluscous animals exhibit very remarkable differences in their form, and the number and position of their external members. Neither head nor foot can be observed in some, the principal organs being enclosed in a bag pierced with apertures for the entrance of the food and egress of the excrementitious matter. In some, whose exterior is still remarkably simple, cuticular elongations, termed tentacula, surround the mouth, and a foot, or instrument of motion, may likewise be perceived. This last organ is in some free at one extremity, in others attached to the body throughout its whole length. In many species there is a head, not, however, analogous to that member in the vertebral animals, and containing the brain and organs of the senses, but distinguished as the anterior extremity of the body, separated from the back by a slight groove, and containing the mouth and tentacula.

In many of the animals of this division, the different members of the body are in pairs, and are arranged, in reference to a mesial plane, into right and left. In some, part of whose organs respect a mesial plane, other parts are single, or in unequal numbers. In other species, the organs, which are not in pairs, are arranged round a central axis, and give to the external form a radiated appearance. But these characters are exceedingly variable and uncertain, as marking the limits of particular tribes; since, in different parts of the same animal, modifications of these forms may be readily distinguished.

2. *Cutaneous System.*—The skin of molluscous animals is more simple in its structure than the same organ in the vertebral animals. The *cuticle* is here very distinct; and, as in other classes, it is thick and coarse, where much exposed, but thin and delicate in its texture, where it lines the internal cavities. A *mucous* web may be detected in the cuttle fish and slug, but of great tenuity. The *corium* is destitute of a villous surface; and on its central aspect it is so intimately united to cellular substance, that its fibrous structure can scarcely be distinguished. The *muscular* web may, in general, be readily perceived. Its fibres proceed in various directions, according to the kind of motion to be executed, and extend or corrugate the skin at pleasure.

The appendices of the skin in this class of animals ought to be carefully studied, as they furnish the most obvious marks for distinguishing species, and for constructing divisions in their systematic arrangement. The appendices of the cuticle are few in number, and perhaps ought to be considered as limited to *hairs.* These, in some species, invest the surface regularly and closely, and may be observed on those which live on land, as well as those which reside in water. In some cases these hairs are as it were united, to form continuous crusts or ridges. These hairs, as well as the cuticle, are liable to be worn off, and in some places can seldom be perceived, unless in early age.

The most important appendix of the skin appears to be *shell.* This part is easily preserved, exhibits fine forms and beautiful colours, and has long occupied the attention of the conchologist. The matter of the shell is secreted by the corium, and the form which it assumes is regulated by the body of the animal. It is coeval with the existence of the animal, and appears previous to the exclusion from the egg; nor can it be dispensed with during the continuance of existence. The solid matter of the shell consists of carbonate of lime, with a small portion of animal matter, resembling coagulated albumen.

The mouth of the shell is extended by the application of fresh layers of the shelly matter to the margin, and its thickness is increased by a coating on the inner surface. These assertions are abundantly confirmed by the observations of Reaumur, (*Mémoires de l'Académies des Sciences*, 1709.) whose accurate experiments have greatly contributed to the elucidation of conchology. If a hole is made in the shell of a snail, and a piece of skin glued to the inner margin, so as to cover the opening, the shelly matter does not ooze out from the broken surface, so as to cover the external surface of the skin, but it forms a coating on its inner surface, thus proving it to have exuded from the body of the animal. When a considerable part of the oral part of the spire of a snail is broken off, and a piece of skin glued to the inner margin, and reflected outwardly and fixed on the body of the shell, the spire is again renewed, and the matter added to the inner surface, thus leaving the skin interposed between the new formed portion and the fractured edge. Similar experiments, repeated on a variety of shells, both univalve and bivalve, by different naturalists, leave no room to doubt that shells increase in size by the juxtaposition of shelly matter from the common integuments.

Each calcareous layer is more or less intimately mixed and enveloped in the animal matter, which we have already alluded to; so that the different layers of successive growth may, by various processes, be distinctly exhibited. If the shell is exposed for a short time in the fire, the animal matter becomes charred, and its black colour, contrasted with the white earthy matter, indicates the different strata: in the same manner as the ivory and enamel of a tooth can be distinguished, when subjected to similar treatment. The same satisfactory results may be obtained by a different process. If the shell be steeped in weak muriatic acid, the earthy matter will be dissolved, and the flakes of albumen will remain as the frame-work of the edifice.

The layers of growth may often be distinguished on the surface of the shell, in the form of striæ, or ridges more or less elevated, but parallel to the margin of the aperture. Other inequalities may likewise be observed on the surface, at right angles to the layers of growth, such as ridges, knobs, and spines. These last derive their origin from the inequalities of the skin on which they have been moulded.

In some univalve shells, the layers of growth parallel to the opening cannot be discerned; when exposed in the fire, there is little darkening of colour; and when dissolved in acids, but a feeble trace of animal matter remains. In the fire, these shells crack in various directions, but exhibit no trace of a scaly structure. By a careful management with the file, the shell may be separated into a central layer contiguous to the skin, and a peripheral layer, both similar in structure, though frequently differing in colour. The shells exhibiting such characters have been termed *Porcellaneous*, from their dense structure, and the fine polish which their surface presents. The formation of shells of this kind must be executed in a different manner from those of the first kind which we have noticed.

If we attend to the form of a young shell of the genus Cypræa of Linnæus, we may perceive that an addition of shelly matter to the margin of the aperture, in the manner in which it is applied in other shells, would not enlarge the cavity, but completely close the aperture. The increase of the shell, (accompanied with a corresponding increase of its inhabitant,) must take place either by absorption of the accumulated shelly matter of the mouth, and an elongation in the direction of the greatest curvature of the shell; or the old shell must be thrown off, and a new one produced, suited to the size of the animal. The former supposition has not been entertained, the latter is now generally received by naturalists. The inner coat of such shells appears to be a transudation from the body of the animal, the outer one applied to the surface by the loose reflected lobes of the cloak. In many other shells, portions of more compact matter than the other parts may be observed, spread on the pillar, and applied to the margin of the mouth by a similar process. Mr. Platt, in support of Reaumur's opinion, that shells are formed by juxtaposition, against the objections of Mr. Poupart, (*Phil. Trans.* vol. liv. p. 43.) erroneously considers the different sizes of the Cypreæ as depending on the thickness of the shell increasing according to age, without admitting a corresponding increase of the dimensions of the contained animal, or cavity for its reception.

The shells of the first kind which we have noticed, from the manner in which they are formed, of cones or layers applied to the inner edge of the margin, and extending beyond it, have an imbricated structure. Those of the second kind, consisting of layers regularly superimposed, have consequently a laminated structure; but between the two kinds there are numerous intermediate links, formed by a combination of the two processes.

In some cases, the hard parts of the skin are not entitled to the appellation of shell, but may rather be considered as horn. Such are the coverings of the mandibles of the Cuttle-fish, the branchial lid of the Aplysia, and the operculum of the Welk. The two last appendices, however, though horny in some species, are shelly in others.

The position of the shell with respect to the constituent layers of the integuments, exhibits very remarkable differences. In some it appears instead of a cuticle, or at least external membrane investing it. In general, however, it occurs between the cuticle and the skin, a position which induces Cuvier, *Lec. d'An. Comp.* xiv. 11.) to consider it as analogous to the mucous web of the vertebral animals. Its intimate connection with the muscular system of the animal, and the protection which it yields, seem adverse to such a conclusion. In many species the testaceous substance occurs in folds of the corium, or inserted in its substance. In this position it never acquires the solid texture which shells exposed, or covered only by the cuticle, exhibit. Those which are thus concealed are in general white; those which are more exposed are frequently coloured. The colouring, however, does not depend on the direct exposure to the light, as some have imagined, for many shells which are destitute of a cuticle are white, while many of those covered with a dense cuticle are finely variegated beneath. The forms of the British species of shells have been described in detail under the article Conchology, where an explanation of the terms by which their different parts are distinguished may likewise be found.

Between the skin and the shell neither vessels nor nerves have been traced; and the manner in which the latter is formed forbids us to expect their existence. Yet the shell cannot be considered as dead matter, so long as it remains in connection with the living animal. In those animals in which the shell is external, there are muscles which connect the animal with its internal surface, and the bond of union being a substance soluble in water, the muscle can be detached by maceration. The analogy between shell and bone is here obvious, although in the one case the connection between the muscle and the bone is permanent, in the other between the muscle and shell temporary, or frequently changed during the life of the animal. But the vitality of the shell, if I may use the expression, is demonstrated from the changes which it undergoes when detached from the animal: The plates of animal matter harden; the epidermis dries, cracks, and falls off; and, in many cases, the colours fade or disappear. We confess ourselves unable to point out the means employed by the animal to prevent these changes from taking place, by any process similar to circulation. It is probably effected by the secretions of the skin, in the same manner as our cuticle and hair are lubricated. When the shelly covering consists of two or more pieces, they are joined together as the articulated bones in the higher classes of animals, by ligaments. These, in some cases, are of great thickness and strength, and, in consequence of their elasticity, assist in the motion of the different parts.

In the molluscous animals, the skin secretes a viscous, adhesive substance, differing according to the medium in which the animal resides, but in all cases calculated to resist its influence. It is probably owing to the lubricating agency of this secretion, that both the cuticle and shell are preserved from decomposition.

The skin likewise secretes the colouring matter by which the shells are variegated. The glands from which it proceeds vary much in different individuals, and even in the same individual in different periods of growth.

The characters furnished by the skin and its appendices, are extensively employed in the systematical arrangement of molluscous animals; nearly all those characters which distinguish the species, and many of those on which genera are established, are derived from the form of the shell, the tentacula, or the colour. This last character, however, is one on which little dependence should be placed.

3. *Muscular System.*—There is nothing peculiar in the muscular system of this class of animals. Where the muscles are inserted in the skin, as is usually the case, that organ is in some cases strengthened by condensed cellular substance; where the muscles are inserted on the shell, although no intervening tendons can be perceived, the existence of a connecting link of a similar nature is rendered probable by the circumstance of boiling water not dissolving the muscle itself, yet detaching it from the surface of the shell. During the growth of the animal, such detachment is frequently performed voluntarily, as it increases in size, and alters its position with regard to the shell.

Molluscous animals preserve themselves in a state of *rest* chiefly by suction and cementation. The organ which acts as a sucker, is in some cases simple, soft, and muscular, as the foot of the snail, while in others it is compound, and strengthened internally by hard parts, as in the arms of the cuttle-fish. The force with which some animals adhere is very considerable, and is strikingly displayed, for example, when we attempt to detach a limpet from the rock.

The rest, which is maintained by cementation, in some cases depends on a glairy secretion, which glues the body of the animal to the substance to which it is disposed to be attached. By such an expedient, the shells of snails adhere to rocks, stones, and plants. It is probable that the bivalve shells of the genus Cyclas, which readily adhere to the sides of a glass, obtain their temporary attachment by means of their glutinous cuticle. In other animals threads are produced, (termed a *Byssus*,) from particular glands, and while one extremity is glued to the rock, the other remains in connection with the animal. But there is an attachment more durable than any of these, which takes place in some shells, they being cemented to rocks or stones by calcareous matter, and retained in the same position during the whole term of their existence.

The locomotive powers of the mollusca are confined to creeping and swimming. The former action is performed by alternate contraction and relaxation of the foot, or muscular expansion, which serves as a sucker, and is analogous to the motion of serpents. The motion of swimming is executed either by the serpentine undulations of the foot and the body, or by the action of tentacula, or expanded portions of the integuments. Many species are aided in swimming by being able to vary the specific gravity of their body at pleasure, and either rise or sink in the water, as circumstances may require. In some, as the Janthina, there is a cellular organ peculiarly destined for this purpose, which may be regarded as in some measure analogous to the air-bladder of fishes. In all these exertions, their progress is proverbially slow. Some bivalve shells have the power of *leaping*, or shifting their position by a sudden jerk, produced by shutting the valves rapidly. This is strikingly displayed in the common Scallop, and is less perfectly exhibited in the river mussels. In a few instances, especially among the slugs, a thread is formed of the viscous secretion of the skin, by which the animal is enabled to suspend itself in the air from the branches of trees.

Although the progressive motions of molluscous animals are comparatively slow, the other muscular actions are executed with ordinary rapidity. The irritabilility of some parts, as the tentacula and branchiæ, is so great, that the protecting movements are executed almost instantaneously, and the organs are contracted or withdrawn into the body. But these rapid exertions are only called forth in the moments of danger; the ordinary movements are all executed with characteristic slowness.

The characters furnished by the muscular system are of great value in the discrimination of species, and in the construction of genera and higher divisions. They are intimately connected with the habits of the animal, and merit the attentive examination of the philosophical naturalist.

4. *Nervous System.*—In the molluscous animals, the nervous system is less complicated in its structure than in the higher classes, and the brain is not restricted in its position to the head. The whole nervous system appears in the form of ganglia and filaments. The principal ganglion, or the one to which the term brain is usually applied, is seated above the gullet or entrance to the stomach. It sends out nerves to the parts about the mouth, to the tentacula, and to the eyes. It may

be considered as analogous to the cerebrum of the vertebral animals. From this ganglion proceed two filaments, one on each side, which, in their descent, inclose the gullet, and unite underneath to form a second ganglion. From this last, which has been compared to the cerebellum, numerous filaments are likewise distributed to the parts around the mouth, and to the other regions of the body. These filaments in some cases again unite, and form subordinate ganglia. In many cases the brain and ganglia are of a white colour, and granulated structure; while the nerves which issue from them are white and uniform. The covering of the first ganglion, which is analogous to the *dura mater*, does not adhere to it closely, but leaves a space filled with loose cellular matter. The tunics of the nerves are equally detached; and as they can be inflated or injected readily, they have led some to suppose that the nerves were hollow, and others, that the tunics were the vessels of the lymphatic system.

The organs of perception, common to the higher classes of animals, do not all exist in an obvious manner among the mollusca. The *touch*, that universal sense, is here displayed in many cases with great delicacy; and the tentacula, and other cuticular elongations which we have already referred to, contribute to augment its resources. The sense of *sight* is by no means universally enjoyed by the inhabitants of this class. In a few species the eye is constructed on the plan of the same organ in the vertebral animals. In general, however, it appears only as a black point, whose peculiar functions can only be inferred from analogy. In many animals there is no trace of an eye, consequently they cannot possess that varied information which the higher animals obtain from that organ. Where eyes exist in this class, they are uniformly two in number. In one tribe only, namely, the cuttle-fish, have the rudiments of the organs of *hearing* been detected. The organs adapted to *smelling* cannot be exhibited, but the existence of the sense is demonstrated by the facility with which they discover suitable food, when placed within their reach. The sense of *taste* exists, but it is difficult to point out the particular parts of the mouth fitted for its residence. But as they select particular articles of food in preference to others, we reasonably conclude that taste regulates the choice.

It is difficult to form an accurate estimate of the knowledge of external objects which molluscous animals can obtain by means of their organs of perception, joined to their powers of locomotion. The kind of life which they enjoy is so widely different from our own; and attempts to tame them, or vary their habits by education, are limited by so many circumstances, that we must ever remain in ignorance of their mental powers or capabilities. M. Lamarck ranges them among his *Animeaux Sensibles*, and considers that, by means of their sensations, they acquire only perceptions of objects, or simple ideas, which they are incapable of combining by any mental process. Had this opinion rested on observations, or even on arguments, it might have been worth while to controvert it, but, as it forms a part of the metaphysical speculations of that zoologist, built upon gratuitous assumptions, it requires no farther notice.

In the classification of the mollusca, the characters furnished by the nervous system, from the difficulty of their detection and exhibition, have never come into use. But those furnished by the organs of perception are highly prized. Of these, the eye is the most obvious and constant. It varies in position in different species; but among individuals of the same species its characters are constant.

5. *Digestive System.*—In the cutaneous, muscular, and nervous systems, traces of a general plan may be observed, according to which they have been constructed in the different tribes. In the organs which remain to be considered, there is less uniformity of structure, each family, almost, being constructed according to a model of its own.

The time when molluscous animals feed has not been carefully attended to. Those which live in the water are beyond the reach of accurate observation. Those that reside on land usually shun the light, and creep forth in the evenings to commit their depredations. During warm dry weather, they stir not from their holes.

The animals under consideration feed equally on the products of the vegetable and animal kingdom. Those which are *phytivorous* appear to prefer living vegetables, and refuse to eat those which are dried. We are not aware that putrid vegetable matter is consumed by them, although many of the snails and slugs are found under putrid leaves and decayed wood. In these places there is shelter from the sun, together with dampness, so that it is difficult to determine whether they sojourn in an agreeable dwelling, or a well-stored larder. Those mollusca which are *carnivorous*, prey on minute animals in a living state, and many of them greedily attack putrid matter.

The means employed by molluscous animals to bring the food within the reach of the organs of deglutition, are exceedingly interesting, both on account of their variety and success. Some are provided with tentacula for securing their prey, and conveying it to their mouth, as the cuttle-fish; others protrude a lengthened proboscis, or an extended lip or tongue, and thus bring their food into the mouth. With many, however, which are fixed to the same spot during the continuance of existence, or only capable of very limited locomotive power, successful efforts are made by the animal to excite currents in the water, (for no permanently fixed animals reside on land,) whereby fresh portions of it are brought in contact with the mouth, and its animal or vegetable contents separated. This action is performed in some cases, as among the bivalves, by the mechanical action of the valves of the shell, aided, in many species, by the syphons, while, in others, it is excited by the motion of articulate feet, as in the bernacles. Where part only of any kind of food is taken into the mouth at once, the lips are possessed of sufficient firmness to cut off the requisite portions, or there are corneous mandibles to perform the office.

In the mouth there is scarcely any process performed analogous to that of mastication in the higher orders of animals. When the food is in the mouth, or entering into the gullet, it is mixed with saliva, as in the more perfect animals. The *salivary glands* in which it is secreted are, in general, of considerable size, divided into lobes, and, in some cases, separated into distinct masses. In many species the existence of a gullet is doubtful, as the food seems to enter the stomach immediately; while, in others, there is a portion of the intestinal canal which has some claim to the denomination.

The stomach, in many cases, is membranaceous, and can scarcely be distinguished from the remaining portion of the intestinal canal. In some cases, however, it is strong and muscular, like the gizzard of a bird, and even fortified with corneous knobs for the reduction of hard substances. In some species the stomach opens laterally into the pylorus, and, in a few instances, possesses a spiral cecum attached to it.

The *liver* in the mollusca is usually of large dimensions, and seated close to the stomach, which it in many cases envelopes. It is divided into numerous lobes, and receives numerous blood vessels. There is, however, nothing analagous to the *vena portarum* of quadrupeds. The *bile* is poured in some into the stomach, and in others into the pyloric extremity of the intestine by different openings. There is no gall-bladder.

There is no division of the canal into small and large intestines, as in the higher classes; or rather, among the mollusca, the relative size of the different parts is reversed. Here the pyloric extremity is usually the largest, while the anal is more slender. The intestine, like fishes, is short in proportion to the length of the body, and, in its course, is subject to few turns. The anus is, in some, placed on one side of the body; in others it is terminal, while, in a few, it opens on the back.

The digestive system is thus more simple in its structure than in the higher classes. It possesses neither pancreas, spleen, nor mesentery. The calls of hunger are often at distant intervals, and the power of abstinence is great.

The characters furnished by the digestive system are extensively used in the inferior divisions of molluscous animals. The form of the lips, the position of the mouth and anus, and the structure of the stomach, deserve to be attentively considered, as indicating the habits of the species.

6. *Circulating System.*—The mechanical process by which the food is converted into chyle has not been satisfactorily traced, nor has the existence of lacteals for the absorption of the chyle been demonstrated. In this class of animals, the veins seem to perform the offices both of lacteals and lymphatics.

The blood in this tribe of animals is white, or rather of a bluish colour. Its mechanical and chemical constitution have never been successfully investigated.

In the employment of the words right and left, to express the relative position of the cavities of the heart in the inferior animals, much confusion must necessarily arise; or rather, other terms must be used to render our descriptions intelligible. The nomenclature of that learned anatomist, Dr. Barclay, appears to obviate all difficulty in reference to the ambiguity of words indicative of position, and to convey in its expressions an idea of the uses of the vessels which are alluded to. Thus the *pulmonic* vessels include all those which bring the blood collected from different parts of the body to the lungs, such as the vena cava, right auricle, right ventricle, and pulmonary arteries. The *systemic* vessels are those which convey the blood from the lungs to the different parts of the body, including the pulmonary veins, left auricle, left ventricle, and aorta. It is our intention to employ these terms as we proceed.

The circulating system of molluscous animals exhibits very remarkable differences in the different classes. In all of them, however, there is both a systematic and a pulmonic system of vessels, as in the higher classes of animals. They may be divided, in reference to their circulating system, into four groups. In the first, the blood is collected from the different parts of the body into a *vena cava*. This vein is divided into two branches, to each of which there is a ventricle attached, and from each ventricle an artery proceeds to the gills or lungs in its neighbourhood. Each of the two divisions of the lungs gives rise to a vein; these terminate in a single ventricle, from whence the blood is transmitted to the different parts of the body. There are here one systemic and two pulmonic ventricles. This arrangement prevails among the *cephalopoda*.

In the second group, the vessels in which the blood has been collected from the different parts of the body proceed directly to the lungs or gills, without the intervention either of auricle or ventricle. The systemic veins which have absorbed the blood from the lungs pour it into an auricle, from whence it passes into a ventricle, to be distributed throughout the body. Here, then, there are neither pulmonic auricles nor ventricles, while there is one systemic auricle and ventricle. This dristribution prevails among the gasteropoda, pteropoda, and inequivalve conchifera. In these last, however, as the oyster and scallop, the auricle is bilobate, making an approach to those of the following division.

In the third group, like the second, there are neither pulmonic auricles nor ventricles, the pulmonic veins proceeding directly to the lungs or gills. The systemic veins, however, terminate in two auricles, these empty their contents into one ventricle; so that there are two systemic auricles and one systemic ventricle. This structure appears in the equivalve *conchifera*.

In the fourth group there are no pulmonic auricles or ventricles, neither systemic auricle; but there are two systemic ventricles. This includes the animals of the *brachiopoda*.

In the last group no pulmonic auricle or ventricle, neither systemic auricle, can be perceived; but there is a single systemic ventricle. Animals of the class *tunicata* exhibit this simple arrangement.

The circulating system furnishes few characters which can be employed in systematical arrangements. The structure of the systemic and pulmonary vessels does not appear to be co-ordinate with any particular plan of external configuration and manner, as we see in the case of the pteropoda and gasteropoda. In these the organs of circulation are very much alike, while the external forms exhibit very obvious differences.

7. *Respiratory System.*—It is probable that all animals, however imperfect, stand in need of a supply of oxygen. In proportion as the circulating system becomes complex, the greater is the quantity of oxygen which is required. In the more perfect animals it has been ascertained, that this oxygen unites with carbon thrown out of the system, and, by converting it into carbonic acid, enables it more readily to escape in the gaseous form. In some animals this production of carbonic acid takes place generally throughout the surface of the skin, while in others particular organs are appropriated to its formation. This is more particularly the case in those animals which, like the mollusca, have pulmonic and systemic blood-vessels When the animal separates the oxygen from unmixed atmospheric air, the organ in which the process is performed is termed *lung*. When the separation takes place in atmospheric air united with water, the organ is termed a *gill*.

The molluscous animals which respire by means of lungs are few in number, and form a very natural tribe, which Cuvier has termed *gasteropodes pulmones*. In them the respiratory organ is simple, consisting of a single cavity, on the walls of which the extremities of the pulmonary artery are spread. This cavity is placed somewhat laterally, and communicates externally by an aperture which the animal can open or shut at pleasure.

The mollusca which breathe by means of gills, exhibit very remarkable differences, in their number, structure, and position. In some cases there is a single cavity communicating by an aperture through which the water enters. The walls of this cavity exhibit an uneven surface, disposed in ridges, which are the gills, and on which the pulmonic artery is expanded. This structure exhibits itself in the Gasteropoda pectini-branchia.

In many cases the gills, though seated in a cavity, like the former, and equally exposed to the contact of the surrounding element, are two in number, one on each side, as in the Cephalopoda. In the Conchifera they are four in number, two on each side, like leaves, and extending the whole length of the body. In these the water is admitted at the pleasure of the animal.

The gills of other mollusca are seated internally, and consist either of arborescent productions, or simple cuticular elongations, within which the pulmonary artery terminates. In some of these, as the Pteropoda, the branchial surface is constantly exposed to the action of the surrounding water; while in others, as the *Gasteropoda, nudibranchia*, and *tectibranchia*, the cuticular expansions, which are analagous to gills, are retractile at the will of the animal.

By means of the characters furnished by the circulating and respiratory systems, the molluscous animals may be divided into several distinct classes. But as we shall employ these characters in the construction of the different divisions to be employed, it is unnecessary, in this place, to enter into their details.

8. *Reproductive System.*—The animals now under consideration present nearly all the modifications of generation which organized bodies exhibit. They are not indeed known to produce their young like buds, as in the fresh-water polypus (Hydra,) nor to multiply by the spontaneous division of individuals, as some Nereidæ and Planariæ. But the three following modes of reproduction have been detected.

In the first the sexes are distinct, as in the higher classes of animals. This mode is exhibited in the Cephalopoda and some Gasteropoda. In the former, however, there is no union of the sexes previous to fecundation. The eggs are first excluded by the female, and the male afterwards covers them with the impregnating fluid, after the manner of fishes. In the Gasteropoda, with the sexes distinct, a union takes place by which the eggs are fecundated. After impregnation, the eggs are either excluded previous to the young issuing from them, or retained in the body of the animal until they are hatched.

In the second the sexual organs are distinct, but they both occur in the same individual; here, however, a union of two individuals is necessary, during which each impregnates and is impregnated. The snail and slug may be quoted as examples.

In the third mode of generation, which may be regarded as the most complete hermaphroditism, there is neither a difference of sex, nor an obvious difference of sexual organs. All that can be detected, is connected with the female parts, and no union of individuals is requisite. This is the mode of generation exhibited by the Gasteropoda scuti-branchia and cyclo-branchia, by the whole of the Conchifera and Tunicata.

In the first division of the first tribe, the female possesses an ovarium and oviduct, and the male a testicle, vas deferens, seminal bag, prostate gland, and penis, together with some accessary organs, whose uses have not been ascertained. In the second division of the first tribe, there is in the female an ovarium oviduct and uterus, and in the male a testicle, vas deferens, and penis.

In the second division, the female organs consist of an ovarium oviduct and uterus, and the male of a testicle, vas deferens, pedunculated vesicle and penis. These organs, all occurring in the same individual, have their openings in what is termed the common cavity of generation, which opens externally. The use of the pedunculated vesicle is not determined. In some species it is attached to the male organs, in others to the female, or to the common cavity.

In the last division, the ovarium is the principal and only organ of generation. In some species it is difficult to discover an oviduct, while in others, not only the oviduct, but its external termination, may be readily traced.

The organs of generation furnish many important characters for classification. The external openings are those which are detected with the greatest facility, but the structure of the internal organs exhibits more varied and driscriminating marks.

9. *Peculiar secretions.*—The molluscous animals are considered as destitute of organs for the production of urine, but they possess various organs for the secretion of peculiar fluids or solids, some of which are useful in the arts.

The coloured fluid, which is secreted by the Cephalopoda and some of the aquatic gasteropoda, appears to consist chiefly of a peculiar mucus united to a pigment whose properties have not been sufficiently investigated. The animals which furnish this secretion, eject it when in danger or irritated, and thus envelope themselves in a dark cloud, and elude the pursuit of their foes. A milky secretion is poured forth over the surface of the skin of some slugs when irritated. Other coloured secretions may likewise be detected in the mollusca, to which we shall afterwards advert.

The threadlike secretions, termed a *byssus*, with which some molluscous animals, especially among the Conchifera, fix themselves to other bodies, appear to be of an albuminous nature. A few species in this division have the power of secreting a *luminous* fluid, which phosphoresces or shines in the dark. Its nature, and the organs in which it is elaborated, have not been investigated. It is probable that some animals, as those which have the faculty of raising or lowering themselves in the water, have likewise the power of secreting *air* into those organs which contribute to their buoyancy. The Janthina vulgaris may here be quoted as an example.

Morbid secretions likewise occur among the animals of this division, chiefly, however, among the Conchifera. The most important of these are *pearls*, so much prized as ornaments of dress.

10. *Condition of the Mollusca.*—Molluscous animals are divided, according to the situation in which they reside, into three groups, which may be termed terrestrial, fluviatile, and marine. Those that inhabit the land belong exclusively to the Gasteropoda. Among these, some prefer open pastures, others the rubbish of old walls, while not a few reside in woods, or among dead leaves and putrid plants. All the animals of this group respire by means of a pulmonary cavity.

The fluviatile mollusca, or such as reside in fresh waters, include not only many Gasteropodous genera, but likewise some belonging to the Conchifera. Among these, some breathe air by means of a pulmonary cavity, and come to the surface to respire. Such species frequent the more shallow ponds and lakes. Others, respiring by means of gills, are less dependent on the shallowness of the water, and consequently reside in different depths.

The marine mollusca include genera of all the classes. Some, as many of the Cirrhipoda, instead of living in the water, prefer a situation where they may only be bathed occasionally with the flood tide. Others burrow in the sand, or adhere to the rocks which are left dry by the receding tide. These are termed littoral species. Many, however, which have been denominated pelagic, reside in the deep, and are seldom obtained but by dredging, or when thrown ashore during storms.

The effect of temperature in regulating the distribution of molluscous animals has not been investigated with any degree of care or success. Over the terrestrial and fluviatile species it probably exercises a very powerful control, greatly limiting their geographical range. In proof of this, it may be stated that the south of France possesses several species not to be found in England, while in England there are a few which have not been detected in Scotland. But among the marine mollusca, the influence of climate is not felt in the same degree. Living in an element whose bulk and motions guard it equally from the extremes of heat or cold, these animals, like the sea-weeds, have a very extensive latitudinal and longitudinal range. Thus, some are common to Greenland and the Mediterranean, others to Britain and the West Indies. The mollusca of the tropical seas, however, differ widely as a whole from those of the temperate regions. Some of the forms appear to be peculiar to warm regions, and in general the intensity of colour decreases as we approach the poles. But as there have been few cultivators of this branch of science, the geographical distribution of the species has been but imperfectly explored. How few parts of either England or Scotland have been surveyed by the eye of the helmonthologist, so that many species whose range is considered as limited, may ere long be found to be extensive.

If the observations are few and imperfect, which have been made on the influence of temperature in regulating the physical distribution of mollusca, we are still in greater ignorance with regard to the power of habit. In the flœtz rocks, the relics of marine and fluviatile mollusca are found mixed in the same bed. This circumstance gave rise to the inquiry, how far the mollusca of fresh water can be habituated to sea water, and *vice versa*. In the account of the proceedings of the National Institute of France for the year 1816, we are informed that M. Beuchant, Professor at Marseilles, has directed his attention to this subject. He found that all these animals die immediately, if we suddenly change their place of abode; but that, if we gradually increase the proportion of salt in the water for the one set, and diminish it for the other set, we can, in general, accustom them to live in a water which is not natural to them. He found, however, some species which resisted these attempts, and which could not bear any alteration in the quality of the water in which they reside. Before much confidence can be placed in the accuracy of these results, it would be desirable that the experiments were repeated by other observers. There are, indeed, many sources of error to be guarded against. When we change animals from fresh to salt water, or from salt water to fresh, we must necessarily derange their motions, by compelling them to reside in a medium of a different degree of density from the one which they have been accustomed to dwell in, and to which the arrangement of the different parts of the body is adapted. By such a change of place, it would be difficult for those which breathe air to come to the surface, and descend again in their new situation. In those with gills, the application of a new kind of fluid to the surface of such delicate organs would considerably influence the function of respiration. The change of situation would likewise be accompanied by a corresponding change of food, and consequently, not merely the organs of locomotion and respiration, but likewise those of digestion, would suffer a derangement in their operations. We know that the power of *suffering* in the animals of this class is very great, and that they survive, though sadly mutilated. Some of the snails will live in a quiescent state for years, without food, and almost without air. Unless, therefore, the animals subjected to these experiments of a change of situation have been observed to grow on the food which it spontaneously yields, to execute their accustomed motions, and, above all, to propagate their kind, we shall be disposed to conclude, that patient suffering has been mistaken for health, and vivaciousness for the power of accommodation.

As connected with the physical distribution of molluscous animals, we may here offer a few observations on the revolutions which they have experienced. From the oldest secondary rocks to the newest alluvial deposits, the remains of the hard parts of these animals may be observed. In the newer situations, these parts are less altered than in the older ones, in which they are frequently changed into calcareous spar, clay, flint, or pyrites. The forms exhibited by the remains in the older rocks are different from those in the newer ones, and intimate that they have belonged to races now no longer existing on the surface of the globe. These remains do not characterize any particular beds or formations, different beds often producing similar remains, and similar beds containing dissimilar fossils, intimating that the physical and geographical distributions of these animals in the earlier parts of the earth's existence, were regulated nearly by the same laws which prevail at present. But into this interesting subject it is impossible at present to enter.

The molluscous animals furnish an agreeable repast to many quadrupeds, birds, and fishes. To man they yield a great deal of palatable and nutricious food. Those which inhabit the sea are held in the highest estimation, while the terrestrial and fluviatile races are generally neglected.

The manner of preparing and preserving the hard parts of the mollusca, has been already given in sufficient detail in the conclusion of our article Conchology, to which we refer the reader. There is only one method of preserving the softer parts—immersion in spirits of wine. But in the execution of this plan some caution is requisite, otherwise the object will appear a shrivelled shapeless mass. The animal should be permitted to die slowly, that the different parts may become relaxed, otherwise the examination of the form of the body at a future period becomes impracticable. A quantity of the spirits ought to be injected into the stomach or other cavities of the body immediately after death, to prevent putrefaction, as it frequently happens, when the body is immersed in spirits without such precaution, that the viscera become unfit for examination, while the integuments remain sound.

In the following general view of the different classes into which molluscous animals have been divided, we shall follow the arrangements of M. Cuvier, modified by the systematical labours of M. Lamarck. Frequent reference will be made to species, natives of the British isles, to enable the curious reader to comprehend the recent improvements which have been effected in this branch of natural history.

I. CLASS.—Cephalopoda.

The animals which are included in this class, are familiarly known by the name of *Cuttle-Fish.* They attracted the notice of the ancients by their curious forms and manners, and appear to have been examined by Aristotle with minute attention.

The cephalopoda, in reference to their external appearance, may be regarded as consisting of two parts. The tunic or sac, which contains the viscera, and the head surrounded by the tentacula. The sac is in some species in the form of a purse, destitute of any appendages, while in others it exhibits fin like expansions. It varies considerably in its consistence, and in some it is strengthened on the back internally by corneous ribs or testaceous plates, in others protected externally by spiral shells. In some species it is connected with the head by an intervening space, which may be regarded as a neck, but in others the tunic and head are continuous behind. In all, it exhibits after death great changes of colour.

On the summit of the head there is a flattened disk, in the centre of which is seated the mouth. Round the margin of this oral disk, which is strengthened by a band of muscular fibres, are placed the arms or tentacula. Beyond this circle of arms, in some species, there are situated two organs, larger in their dimensions than the arms, which may be denominated feet. Both the arms and feet are covered on their central aspect with numerous suckers, by which they are enabled to attach themselves to different bodies, and to seize their prey, and in their axis both a nerve and artery may be observed. These arms and feet are capable of being moved, at the will of the animal, in every direction, and are the organs by which progressive motion is performed. In the space between the head and tunic in front, there is an opening or *funnel* with a projecting aperture. This funnel opens into the cavity of the sac, and serves to convey water to the gills, and to carry off the different excreted matters.

The brain in the cephalopoda is contained in an irregular hollow ring in the cartilaginous border of the oral disk. This cartilage is thickest on the dorsal aspect, and contains the parts which have been denominated cerebrum and cerebellum, the remaining part of the canal being occupied with the collar, which surrounds the esophagus. The nerves, which proceed directly from the brain to the parts which they are destined to influence, are few in number. From the cerebrum issue a few small nerves, which go to the mouth, and the base of the feet—others which go to form ganglia at the mouth, and others for supplying the feet. The cerebellum, besides furnishing the collar which encircles the gullet, contributes to the formation of the large ganglia which supply the arms—the optic and auditory nerves—those for the funnel, the tunic, and the viscera. From the size of the animals, the ganglia of the nerves are very distinctly displayed. The anastomosing branches of the nerves of the arms are likewise conspicuous. Each nerve at the base of each foot sends out two filaments, one to the nerve of the foot on each side. In this manner a chain of nerves is formed round the base of the feet, probably calculated to enable them to act more readily in concert.

From the abundant distribution of nerves to the different parts, it appears probable that the sense of touch exists in a tolerably perfect manner. There is no proof of the development of organs for the display of the senses of smell and taste.

The cephalopoda are furnished with two eyes, one on each side of the head. The external membrane on the inner side, which may be compared to the *sclerotica*, differs in many particulars from the covering of the same name in the eyes of the vertebral animals. While it surrounds the contents of the eye from the entrance of the optic nerve to the pupil, it is greatly separated from the choroides. Immediately within its cavity, there is a bag with a peculiar membraneous covering, which contains numerous glandular bodies, similar to the milt of fishes, by which the eye is supported, and which probably act as secreting organs, (although M. Cuvier could not detect any excretory canals,) and likewise an expansion or ganglion of the optic nerve. The concave or anterior surface embraces the *choroides*. This membrane, after embracing the vitreous humour, forms a zone or diaphragm, which may be compared to the ciliary processes, with an aperture in the centre for the reception of the crystalline lens. The circular margin of this aperture is lodged in, and intimately united with a circular groove, by which the lens is divided into two unequal hemispheres. Its central surface is coated, as in the higher classes of animals, with the coloured mucous pigment, which has been denominated *pigmentum nigrum*. In the cephalopoda, however, it is of a purplish-red colour.

The optic nerve, after entering the sclerotica, expands into a large ganglion, from the peripheral surface of which issue numerous nervous filaments. These pierce the choroides by as many holes, and go to form by their reunion the retina. This important membrane extends to the ciliary zone, and like it appears to unite itself with the groove of the lens.

The vitreous humour is contained in a peculiar vesicle, having the lens seated in a concavity on its external surface. The lens divides easily into two parts, the line of separation being the groove which receives the ciliary ligament. Each portion consists of a number of concentric layers of variable thickness, composed of radiated fibres, becoming less and less distinct towards the centre, near which the laminated and radiated appearances cease to be perceptible. An imperfect representation of this structure is given by Sir E. Home, probably from preparations by Mr. John Hunter, in the *Phil. Trans.* vol. lxxxiv. tab. 5 p. 26.

The conjunctiva supplies the place of a cornea, and covers directly the crystalline lens, as there is no aqueous humour. This membrane in some is continuous with the skin, but in others there are imperfect eye-lids, formed by its duplicature, previous to passing over the lens. The skin, at the opening of the pupil, formed by the sclerotica, in the absence of an *uvea* and *iris*, is strengthened by a membrane which appears to be muscular, and probably assists in the contraction or enlargement of the aperture.

The animals of the cephalodous class, besides containing complicated eyes, are likewise furnished with ears. These are situated in the annular cartilage which supports the arms. In this cartilage there are two cavities. In each of these there is a bag filled with a gelatinous transparent fluid, and containing a calcareous substance, differing in its consistence, according to the species, from the brittleness of starch to the hardness of bone.

The auditory nerve penetrates the walls of this labyrinth, and ramifies on the membranous bag which it contains. There is no external opening, nor any apparent alteration in the thickness of the investing integuments.

The digestive system of the Cephalopoda exhibits several appearances by which it may be distinguished. The arms which surround the mouth, seize the animals which are to serve as food, and bring them to the mouth. The mouth is situated in the centre of the disk, round which the tentacula are arranged. It is surrounded with a slight fold of the skin, which may be compared to lips, and which is rough on the central aspect. Within these are the two mandibles, of a deep brown colour, hard horny consistence, and in form resembling the beaks of a parrot. Where free, they are conico-tubular, but where covered, they are open at the central side. The under beak, unlike the same organ in birds, is the largest, the most crooked, and embraces the upper, or the one on the dorsal margin of the mouth. These jaws are merely able to open and shut, as they possess no lateral motion. They are supported by the muscular bed of the mouth, which serves as a mould to fill the cavity towards the point. The tongue is situated between the beaks, and is armed with reflected teeth. These teeth, in consequence of the undulatory motion of the substance of the tongue, expedite the progress of the food into the gullet.

The salivary glands are four in number; the first pair, seated on each side the muscular bed of the mouth, are each divided into numerous lobes, whose excretory ducts pour their fluid into the beginning of the gullet. The second pair, seated lower down and below the eyes, are not so much divided, and send out each a canal. These unite, and pour their contents into the mouth.

The gullet is furnished with a lateral expansion, not unlike the crop of gallinaceous birds. The stomach is muscular, like the gizzard of fowls, and the cuticle is thick, and separates easily from the other membranes. At the pyloric opening of the stomach, there is another aperture equally large, which leads into the *spiral stomach*, or cæcum, as it has been improperly termed by some anatomists. It may with greater propriety be denominated the duodenum, as it performs some of the offices of that part of the gut in the higher orders of animals. This stomach is conical, closed at the distal extremity, and performs about a turn and a half, like a spiral shell. Its inner surface is covered with a ridge, which traverses it in a closely spiral direction. The bile flows into it near the apex, and towards its base, glandular orifices pouring out a thick yellow fluid may be observed. The intestine, after leaving the pyloris, in some species makes one or two turns, in others it proceeds directly to the anus. This opening is seated at the base of the funnel, on its posterior or dorsal side.

The *liver* is of considerable size, of an orange-yellow colour, and of a soft and spongy texture. It gives rise to two hepatic ducts, which proceed to the extremity of the spiral stomach, where they empty the orange-coloured bile which they contain by a common orifice.

The organs of circulation consist merely of veins and arteries, which we distinguish into pulmonic and systemic. The veins, which have their origin in the feet, mouth, and annular cartilage, coalesce, and form two branches, which afterwards unite into a common trunk. This vessel, after descending through part of the viscera into the abdomen, divides into two branches, each of which may be considered as a *vena cava*, conveying the blood to the lateral hearts. Each vena cava, at its origin, is joined by an equally large vessel, which empties its contents in a direction nearly at right angles with the former. These veins arise in the stomach, intestines, liver, and organs of generation. The vena cava receives a second large vessel, nearly in the same direction as the first, which has its origin in the tunic and the supports of the branchiæ. From the size of the vena cava, in consequence of the union of these two branches, and the appearance of muscular ridges on its inner surface, it has been compared by some to an auricle.

On each side, in the common cavity of the tunic, and near the gills, an aperture may be observed, the entrance to a bag or cavity. Each cavity is traversed by the vena cava of that side, and in its passage exhibits a curious confirmation. The surface of the vein is covered with spongy glandular bodies of different shapes. These, upon being pressed, pour out an opake yellow mucous fluid. Within, these glands communicate by means of very wide ducts with the cavity of the vein. Indeed, when air is blown into the vein, it readily passes through the glands into the bag, and from thence into the cavity of the tunic; and when air is blown into the bag, it likewise penetrates the gland, and passes through into the veins. The arteries with which these glands are furnished are comparatively minute.

It appears probable that these glands separate some principle from the blood, and that this is conveyed away by the ejection of the water from these venous bags into the common cavity. Were it practicable to analyse the yellow mucus which these glands contain, some light might be thrown on this subject. Indeed, it appears not improbable that this arrangement is analogous in its functions to the urinary system in the most perfect classes.

Each vena cava enters its corresponding lateral heart or ventricle, through an intervening valve. Each lateral heart is situated at the base of each gill, is pear-shaped, black, moderately thick, with numerous pits on its inner surface. Its narrow end terminates without any valvular structure in the pulmonary artery. In the genus octopus, the lateral hearts are naked; but in the generalolego and sepia, there is suspended from each, by a slender footstalk, a spongy round body, which is concave beneath. The footstalk consists of fibres, which are attached to the surface of the heart, but there is no communication by ducts or vessels. The use of this organ is unknown.

The animals of this class continually reside in the water, and respire by means of gills or branchiæ. These are double, one on each side, corresponding with the lateral pulmonic ventricles. Each gill is connected at its opposite sides to the tunic, by means of fleshy ligamentous bands. Between these, the double leaves of the gills are arranged in an alternate series. Each leaf is supported by a footstalk from the band, and is subdivided into smaller leaves, to expose a greater surface to the water.

The pulmonary artery passes along this band, sends a branch into each footstalk, which, penetrating the substance of the gills, conveys the blood to its different divisions.

The systemic veins depart from the gills at the opposite extremity. These unite at the inferior band, and from each gill a vessel proceeds to the single central or systemic heart or ventricle. In some of the animals of this class the systemic veins are somewhat enlarged, and assume the appearance of auricles. The two pulmonary, or rather the systemic veins, enter the heart at the opposite side, each at the termination being furnished with a valvular organization.

The systemic heart is white and fleshy, and differs according to the genera in its form, being in the Octopus semicircular, but in the Loligo and Sepia lobed. Besides giving rise to a large aorta, or principal artery, two smaller ones likewise proceed from its cavity. These arteries are furnished at their entrance with valves.

The sexes in the Cephalopoda are distinct, the male and female organs being found on different individuals. There is not, however, any external mark by which they may be distinguished. M. Cuvier found that the males of the Octopus were scarcely a fifth part so numerous as the females.

The male organs of generation consist of the following parts. The *testicle* is a large white glandular purse, containing numerous fringed filaments, from which the seminal fluid is secreted. This fluid passes out of the testicle, by a valvular opening, into the *vas deferens.* This canal is slender, and greatly twisted in its course, and opens into a cavity which has been compared to the *seminal vesicle.* The walls of this last cavity are strong and muscular, and disposed in ridges. Near the opening at the distal extremity of this sac, is an aperture, leading into an oblong glandular body, regarded as exercising the functions of a *prostate gland.* Beyond this lies a muscular sac, divided at the top, where it opens by two ducts, but connected at the base. In this sac are numerous white thread-like bodies, terminated by a filament, but unconnected with the sac. In the interior they consist of a spiral body, connected at each extremity with a glandular substance. When these bodies are put into water, they twist themselves in various directions, and throw out at one of their extremities an opaque fluid. These motions are not excited by placing them in oil or spirit of wine, but they may be exhibited by immersing in water those which have been kept for years in spirits.

These bodies, first observed by Swammerdam, and afterwards by Needham, have been regarded by some as demonstrating the truth of the vermicular theory of generation; by others, they have been considered as analogous to the pollen of plants—that their tunic is in part soluble in water, and when they are thrown into that fluid, they speedily burst, and spread their impregnating contents over the eggs of the female. Although this last conjecture is plausible, and countenanced by the circumstance that these vermicular bodies are only found at the season of reproduction, the subject is still involved in obscurity. Are these bodies produced in the testicle, and only brought to this bag when nearly ready for exclusion; or, if the product of the bag itself, by what means are they nourished?

The male organs terminate in a cylindrical fleshy body termed the penis. This is hollow within, and ribbed with muscular bands. Near its base it receives one of the ducts of the vermicular sac, continuous with the one from the prostate gland, forming its canal, and toward the apex the other duct. It projects but a short way into the cavity of the great bag, into which it empties its contents. These pass out of the body at the funnel-form opening in the throat.

The female organs of generation consist of an ovarium and oviduct. The ovarium is a glandular sac, to which the ova are attached by footstalks. The opening by which they issue from the ovarium is wide, and the oviduct (in the Octopus vulgaris and Loligo sagittata,) after continuing a short way simple, divides into two branches, each having its external aperture near the anus. The oviducts are furnished within with muscular bands, and a mucous lining, and encircled with a large glandular zone, destined, probably, to secrete the integuments of the eggs. In the Loligo vulgaris, and the Sepia, the oviduct continues single. Besides these organs, the Loligo vulgaris and sagittata, and the Sepia, have two large oval glandular bodies, divided by transverse partitions, with their excretory ducts terminating at the anus, whose use is unknown.

The eggs, whose peculiar form has been already noticed, pass out of the funnel, after which they are supposed to be impregnated by the male, according to the manner of fishes.

The *inky fluid* now remains to be considered, as the most remarkable of the peculiar secretions of this tribe of animals. The organ in which this fluid is secreted is spongy and glandular. In some species it is contained in a recess of the liver, which has given rise to the opinion that the coloured fluid which it secreted was bile. In other species, however, this gland is detached from the liver, and either situated in front or beneath that organ. The excretory canal of this gland opens in the rectum, so that the fluid escapes through the funnel. It mixes readily with water, and imparts to it its own peculiar colour. When dried, it is used as a pigment, and is considered as the basis of China ink.

The Cephalopoda are all inhabitants of the sea. They are widely distributed, occurring in the arctic as well as the equatorial seas. In the latter, however, they grow to the largest size. It is reported, that in the Indian Seas, boats have been sunk by these animals affixing to them their long arms, and that they are dreaded by divers.

In the classification of the animals of this class, many difficulties present themselves, in consequence of the imperfect descriptions of their external characters, given by naturalists. In the following general view we shall endeavour to distribute them into natural groups and genera, without attempting an enumeration of all the species. Such only as are inhabitants of the British seas shall be particularly enumerated.

The Cephalopoda appear to constitute two great divisions, distinguished by the support which is afforded to the abdominal sac. In the first, which may be termed *sepiacea*, the sac is strengthened by horny or testaceous processes, unless where the habits of the animal renders such protection unnecessary. The second division, which may be termed *Nautilacea*, comprehends those animals furnished with a multilocular shell. These two divisions constituted in the Linnæan system the two genera, Sepia and Nautilus.

1. Sepiacea. Although the animals of this division agree in many external and internal characters, there are, however, considerable differences of structure to warrant their subdivision into two orders. In the first order will be included such as are furnished with only eight arms, and whose sac is destitute of fin-like expansions, and either simple, or strengthened behind in the interior by two short corneous processes. The head is united to the sac behind, without the intervention of a neck. The suckers have soft margins. The second will comprehend those which are furnished with eight arms and two feet, whose sac is furnished with fin-like expansions, and strengthened internally by corneous or testaceous ribs or plates. The head is divided from the sac on all sides by a neck. The suckers have a corneous margin.

The first order might admit of some subordinate divisions, founded on differences in the habits of the animals. It will suffice that we notice merely the genera. These are three in number, Octopus, Eledona, and Ocythöe.

1. *Octopus*. This genus, so named by Lamarck, is the Polypus of Aristotle. All the arms are of equal size, and the suckers with which they are furnished are sessile, and arranged in a double row on their central aspect. The oviduct is double, and the margin of the anus is simple.

There are several species belonging to this genus; but the one with which naturalists have been longest acquainted is the Sepia octopodia of Linnæus, or *Octopus vulgaris*, of modern arrangements. There is a figure of it in Pennant's British Zoology, vol. iv. p. 53, No. 44. Tab. xxviii. The body is short, and rounded at the tail. The arms are nearly six times the length of the body, and furnished with about two hundred and forty suckers. This species inhabits the British seas, and has been termed Poor Cuttle, Pour-contrel, and Preke. It was first recorded as a native by Merrat in his Pinare, p. 191. It is occasionally dredged up from the oyster-beds in the Frith of Forth. Baker describes a species analogous to this in the *Philosophical Transactions* for the year 1757, p. 777, Tab. xxix.

2. *Eledona*. This genus was known to Aristotle. It agrees with the preceding genus in having all the arms similar, but it is distinguished by each arm having only a single row of suckers.

Lamarck has figured and described two species of this genus in the *Mem. de la Soc. d'Hist. Nat.* One of these, a native of the Mediterranean, is remarkable for giving out an odour like musk.

3. *Ocythöe*. In this genus, so named by M. Rafinesque, there are two of the arms furnished at their inner extremities with membranaceous expansions. The suckers, which are in a double row, are supported on short footstalks. Dr. Leach observed "four oblong spots on the inside of the tube, resembling surfaces for the secretion of mucus; two inferior and lateral, and two superior, larger, and meeting anteriorly. On the rim of the sac, immediately above the branchiæ, on each side, is a small, short, fleshy tubercle, which fits into an excavation on the opposite side of the sac. This character, which, with slight modifications, is common to this genus, to Loligo and Sepia, does not exist in the Polypus." *Phil. Tr.* vol. cvii. p. 295.

The animals of this genus were for a long time considered as the fabricators of the shell termed *Argonauta*, or the Paper Nautilus, never having been found in any other condition than occupying the cavity of that shell. The clustered eggs (which they have in common with the other cephalopoda,) have likewise been found in the cavity at the top of the spire, the female occupying the mouth. They are capable of raising themselves to the surface, and of floating and moving there by means of their winged feelers, aided probably by secreted air in their body. Upon the approach of danger they sink rapidly to the bottom.

Although this animal has never been found but in the cavity of the shell of an Argonauta, there are various circumstances which confirm us in the belief, that it is not the fabricator of the shell, but, like the Hermit crab, occupies the deserted dwelling of another animal, which has not as yet fallen under the observation of naturalists. The body of the animal does not conform in shape to the cavity of the shell, nor to all its irregularities of surface. There is no muscular or ligamentous attachment between the animal and the shell, so that it is able to leave the shell at pleasure, as it was observed to do by the late Mr. Cranch, zoologist to the Congo expedition. The reader who is desirous of farther information on this subject, may consult Dr. Leach's *Observations on the Genus Ocythöe of Rafinesque;* and Sir E. Home on the *Distinguishing characters between the ova of the Sepia and those of the vermes testacea that live in water;* in the *Philosophical Transactions for the year* 1817, art. xxii. xxiii.; and a paper by Mr. Say *On the Genus Ocythöe* in the *Phil. Trans.* 1819, art. vii.

The genera which belong to the *second* order are only two in number, viz. Sepia and Loligo. In both, the suckers on the arms are pedunculated, and their margin strengthened by a corneous ring furnished with teeth, and the margin of the anus is surrounded with appendages or tentacula. The two feet with which the animals of this order are furnished are nearly similar in their structure to the arms, but considerably larger in their dimensions. They take their rise on the ventral side of the mouth, between that organ and the funnel.

4. *Sepia*. In this restricted genus the sac is furnished on each side throughout its whole length with a narrow fin, and strengthened on the back by a complicated calcareous plate, lodged in a peculiar cavity. The suckers are irregularly scattered on the arms and feet.

The calcareous plate has been long known under the name of *cuttle-fish bone*. It is somewhat ovate, flatly convex on both sides, and thickest where broadest. The superior half, or the one next the head, is the longest, rounded at the extremity, and thin. The inferior portion becomes suddenly narrow, and ends in a point. It may be considered as consisting of a dermal plate, concave on the central aspect, having its concavity filled up with layers which are convex on their central aspect.

According to our observations the dermal plate appears to consist of three different laminæ, arranged parallel to one another. The external or dorsal layer is rough on the surface, and marked by obscure concentric arches towards the summit, formed by minute knobs, which become larger towards the base, where they appear in the form of interrupted transverse ridges. It is uniform in its structure, and the tubercles possess a polish and hardness equal to porcellaneous shells, although they blacken speedily when put in the fire, and contain a good deal of animal matter. On the central side of this layer is one flexible and transparent, similar to horn, and smooth on the surface. The third layer is destitute of lustre, and in hardness and structure resembles mother of pearl shells.

The layers which fill the concavity of this dermal plate are slightly convex on the central aspect, and are in part imbricated. Each layer is attached to the concave surface of the dermal plate by the upper extremity and the two sides, while the inferior or caudal extremity is free. The inferior and first formed layers are short, and occupy the base and middle, and rise from the plate under a more obtuse angle than the new formed layers, which are both the longest and the broadest.

Each layer, which is about one-fiftieth of an inch in diameter, consists of a very thin plate, whose dermal surface, when viewed with a magnifier, exhibits numerous brain-like gyrations. From the ventral surface of this plate arise numerous perpendicular laminæ, which, when viewed laterally, appear like fine parallel threads, but, when examined vertically, are found to be waved, and fold upon themselves. Next the plate they are thin, and not much folded; but towards their other extremity, they become thicker, striated across, and more folded, with irregular margins. On the thick tortuous even ends of these laminæ, the succeeding plate rests, and derives from them the peculiar markings of its surface. These laminæ are closely set, irregularly interrupted, and occasionally anastomose. M. Cuvier (*Mem. sur la Seiche*, p. 47.) states, erroneously, that these laminæ are hollow pillars disposed in a quincunx order.

The term bone has been improperly applied to this complicated plate; "for," (according to Mr. Hatchett, *Phil. Trans.* vol. lxxxix. p. 321.) "this substance, in composition, is exactly similar to shell, and consists of various membranes hardened by carbonate of lime, without the smallest mixture of phosphate."

This bone was formerly much prized in medicine as an absorbent, but is now chiefly sought after for the purpose of polishing the softer metals.

The most remarkable species of this genus is the *Sepia officinalis*, which is distinguished from the others by its smooth skin. It inhabits the British seas, and, although seldom taken, its bone is cast ashore on different parts of the coast, from the south of England to the Zetland isles.

5. *Loligo*, or Calamary. This genus, the larger species of which are known to the fishermen under the denominations Sleeve-fish, Hose-fish, and Anchor-fish, is distinguished from the former by having the sides of the sac furnished only partially with fins. The dorsal plate is flexible and corneous, imbedded in the substance of the sac, and is multiplied with years. The suckers are disposed on the arms and feet in a double row.

The species of this genus have not been investigated with much care. Four sorts have been found in our seas, which are probably the types of as many different genera. In two of these the sac is cylindrical above, and compressed towards the tail, with which the fins on each side are united.

In the *Loligo vulgaris*, the fins, together with the tail, form a rhomboidal expansion. The feet are nearly of the same length with the body, and covered with suckers only near their distal extremity. There is no eye-lid. The bone is elliptical, elongated, and produced at the upper extremity, with a groove along the middle. The appendage to the stomach is straight, and the oviduct is single.

This species is described and figured by Borlace, in his *Natural History of Cornwall*, p. 260. Tab. xxv. f. 27; and by Pennant in the *British Zoology*, vol. iv. p. 53. No. 43. Tab. xxvii.

In the *Loligo sagittata*, the fins, with the tail, form a triangular expansion; the feet are shorter than the body, and covered with suckers nearly to their base. There is a duplicature of the skin round the eye, forming an eye-lid. The bone is narrow, thin, expanded at both ends, and strengthened by two marginal ribs, and one in the centre. The appendage to the stomach is spiral, and the oviduct double.

This species has hitherto, in this country, been confounded with the preceding. It is, however, the one alluded to by Monro, secundus, in his *Structure and Physiology of Fishes*, p. 62. tab. xli. xlii. His specimens were probably obtained from the Frith of Forth. The same species has occurred to the writer of this article in the Frith of Tay.

In the two remaining species the fins which occur near the tail are not continued to its extremity. The *Loligo media* has the sac long, slender, and rounded. The fins on each side are of an elliptical form, and the tail is produced beneath into a point. This appears to be a rare species. It is figured by Pennant in his *British Zoology*, vol. 4, tab. xxix. No. 45.

In the *Loligo sepiola*, the body is nearly of equal dimensions in length and breadth; the fins are thin and rounded, and the outline of the tail semicircular. It is figured by Pennant in the *British Zoology*, vol. 4. tab. xxix. No. 46. This species appears to be rare. It is recorded by Pennant as having been taken off Flintshire. A specimen now before us was obtained in the Frith of Forth, at Kirkaldy, by Mr. Chalmers, surgeon of that town.

Various species of the Sepiacea were formerly used as food; and Aristotle informs us that they were considered in the best condition for the table when nearly ready for spawning. The modern Italians and Greeks are said to use them still as an article of diet, and to consider the eggs as a great delicacy. In our own country, Mouffet considered them excellent meat, when boiled with wine and spices.

The animals of the second great division of the cephalopoda may be considered as nearly unknown. The shells were united by Linnæus in one genus, which he termed Nautilus; but, in consequence of their peculiar characters, they have been sub-divided into many new genera. The animals belonging to two of these modern genera, spirula and nautilus, which both belong to the spiral multilocular tribe, have been imperfectly described.

The *shell* of the *Spirula* has the whorls separate, the mouth orbicular, the chambers perforated by a tube, and the last cell produced into a tube. The *animal* resembles the Sepia, and the shell is concealed under the skin, and occupies a similar situation to the cuttle-bone.

The animal of the *Spirula vulgaris* appears to be very common in the West Indies, as the chambered spiral extremity of the shell is frequently brought to this country.

In the *shell* of the restricted genus *Nautilus*, the turns of the spire are contiguous, the last whorl embraces the others on the sides, and the chambers are perforated by a tube. The animal of the *Nautilus pompilius*, according to Rumphius, lodges in the last chambers, and is fixed by a ligament which descends into the tube. The arms which surround the mouth are destitute of suckers.

Among the minute shells which occur in the roots of sea-weeds, on old shells, corals, and sertulariæ, are many genera of multilocular testacea, some of which have been described in the article Conchology. Guided by analogy, naturalists have been disposed to consider these as the productions of cephalopodous mollusca. Their inhabitants, however, have not been examined, and the task of doing so will be very difficult, as they are all very minute. When it is considered that a gasteropodous mollusca breathing air, Segmentina (Nautilus of Lightfoot) palustris, has its shell divided into chambers by transverse partitions, and that the shells of some of the Annelides likewise exhibit appearances of being multilocular, the analogy loses its value, and we are disposed to conclude that the true place in the systematical arrangement of animals, for the introduction of these minute shells, remains to be ascertained. Indeed, until the animals of the Spirula and Nautilus shall have undergone a more minute investigation, the characters by which they are distinguished must be viewed with suspicion.

Many species of multilocular testacea occur in a fossil state, which are usually considered as the remains of cephalopodous mollusca. Some of these are spiral like the Nautilus, others are orbicular like the Miliola, while in a third the chambered shell is nearly straight, as in the Orthocera.

As intimately related to the last mentioned genus, we may here take notice of the *belemnite*. In this fossil the apex is solid, with a groove or fold on one side, and at the thick end there is a conical cavity filled with a shell divided into chambers, which are penetrated by a pipe. If we regard this body as the remains of a cephalopodous animal, we may consider the exterior solid extremity to have been a corneous covering, and the chambered alveolus as the seat of the body of the animal, which likewise enveloped the base. That the solid base was hard, and not muscular, like the sac of the Sepiacea, is obvious from the surpulæ which have been found adhering to its surface, and which probably took up their residence after the death of the animal, and the destruction of the soft covering. That the solid part was different in its nature from shell, appears probable from the circumstance that the latter, when mineralized, is usually converted into calcareous spar, while the former appears of a fibrous structure.

The alveoli of the belemnite bear so near a resemblance to the species of Orthocera, that some have concluded that the latter were originally parts of a belemnite. Several circumstances, however, militate against this opinion. Orthoceratites are frequently found fossil where there are no vestiges of belemnites, and even appear to occur in older rocks. Many recent species of the genus Orthocera have been found on our own shores without the vestige of an external covering. Had they possessed any such solid apex, like the belemnite, it is probable that it would have been detected in the recent kinds, since it is sufficiently durable to retain its form in the solid strata. The shell of the belemnite was probably, in some respects, internal—that of the orthocera was probably external, or covered only by the common integuments. The views here given do not greatly differ from those of Mr. Plat, in the *Philosophical Transactions*, vol. liv. p. 38.

Class II.—PTEROPODA.

This class was instituted by Cuvier, for the reception of a few genera, whose peculiar characters indicated the impropriety of suffering them to remain in any of those categories which had been previously established. All the species are small in size, and the attempts which have been hitherto made to investigate their internal structure have, in a great measure, failed in explaining the functions of the organs which are exhibited. The valuable papers of Cuvier, on the Clio, Pneumodermon, and Hyalea, include nearly all the accurate information on the subject of which naturalists are in possession.

The general form of these animals is somewhat ovate. The tunic appears in some genera, as the Clio and Pneumodermon, to be double, the external one soft and thin, the internal exhibiting a fibrous structure, corresponding to the muscular web of the skin of the higher classes. In these animals, however, these two layers are unconnected throughout the greater part of their expansion. In some, as the cymbulia, the tunic is cartilaginous, while in others it is strengthened by a shell. In these last, the shell in the Limacina is a spiral univalve, covering the abdominal viscera, and in the Hyalea, where it serves the same purpose, it approaches in character a bivalve shell. It is, however, destitute of a hinge, the two valves being united together at their caudal margins, and there is no appearance of a transverse adductor muscle.

The organs of motion in all the genera consist of two fins, or membranaceous expansions, seated one on each side the head. They have no foot wherewith to crawl, nor any suckers by which they can adhere to objects. They are therefore free animals, moving about in the water by means of their fins, and possessing, probably at the same time, a power of varying their specific gravity, as they are capable of varying, to a certain extent, the form of their bodies, and of enlarging or reducing their dimensions. There is nothing peculiar in their nervous system.

Their organs of digestion differ greatly from those of the cephalopoda, which we have already considered. They are generally regarded as destitute of eyes and ears. Their tentacula are either seated on the head, forming two complicated branches of filaments, or spread along the margin of the tunic. There are no arms for seizing the food. The mouth, however, is furnished with lips, and, in some, an appearance of a tongue at the entrance of the gullet. The salivary glands are two in number, lengthened, descending a considerable way into the abdomen, and pouring their contents, by means of their excretory canals, into the cavity of the mouth. The gullet, after being encircled by the nervous collar, suffers an enlargement, which has been termed a crop, contiguous to which is the stomach. Both these cavities exhibit muscular ridges on the inner surface. The liver surrounds the stomach, and is intimately united with its contents, and pours in its bile by numerous pores. The intestine is short, and after making one or two turns, ascends and terminates in the neck near the mouth.

The circulating system in this class has been but very imperfectly investigated. The pulmonic vessels are unknown, but systemic veins, a single auricle, ventricle, and aorta, have been detected. The heart, in some, is situated on the left, in others on the right side of the body.

The respiratory or aërating organs, exhibit very remarkable differences. In the Clio they are in the form of a fine net work on the surface of the fins; in the Pneumodermon they are conjectured to form leaf-like ridges on the caudal extremity of the body, or if these ridges are to be considered as particular kinds of fins, the gills may be sought for on the membranaceous expansions of the neck. In the Hyalea the branchiæ form a complex band on each side the body, at the lateral opening of the shell.

The animals of this class are all hermaphrodites. There is a common cavity, a vesicle, penis, vas deferens, and testicle, together with an oviduct and ovarium. These open near the mouth on its ventral margin. There is nothing known with respect to the appearance of the eggs, the period of propagating, or the form of their young.

All the animals of this class inhabit the sea. Some of those, as the Clio and Limacina, frequent the arctic regions, and afford the whale a great part of its sustenance. None of the species of the class have hitherto been detected in the British seas.

M. Cuvier, in his *Règne Animal*, II. p. 378, subdivides the genera of this class into two orders. The animals included in the first are furnished with a head distinct from the body, and are arranged under the five following genera; Clio, Cleodora, Cymbulia, Limacina, and Pneumodermon. Those of the second division, which are destitute of a head, constitute only one genus, named Hyalea.

1. *Clio.*—In this genus the body is ovate and elongated, the tunic membranaceous, and the head divided into two lobes, whose summits are furnished with tentacula. The mouth is transverse, with two lateral longitudinal lips. On each side the neck arise two blunt, conical, fin-like expansions, with a fine reticulated surface, considered as serving the double purpose of fins and branchiæ. The anus and orifice of generation terminate under the base of the right branchia. The viscera do not fill entirely the cavity of the inner bag. The gut makes only one fold. The existence of eyes has not been ascertained.

The genus Clio was originally instituted by Brown, in his *Natural History of Jamaica*. It was afterwards embraced and modified by Linnæus and Pallas, in such a manner as ultimately to exclude the species for whose reception Brown originally formed it. It contains two species, the most remarkable of which is the *Clio borealis*. Mr. Scoresby, in his valuable work on the Arctic Regions, lately published, states (vol. i. p. 544.) that it occurs in vast numbers in some situations near Spitzbergen, but is not found generally throughout the arctic seas. In swimming, it brings the tips of the fins almost into contact, first on one side, and then on the other.

2. *Cleodora.*—This genus was instituted by Peron, for the reception of Brown's species of Clio. The body is covered with a triangular pyramidal tunic, carrying two membranaceous wings, between which is the mouth, furnished with a semicircular lip.

The species whose characters have been most fully developed, is the Cleodora pyramidata. *Brown's Jamaica*, p. 386. tab. 43. fig. 1.

3. *Cymbulia.*—The tunic of the species of this genus is trough-shaped, and cartilaginous. The fin-like expansion is single, divided into three lobes, one of which is small, with two tubercles, and a minute fleshy beard. This genus was instituted by Peron, in *Annales du Museum*, vol. xv. tab. 3. fig. 10, 11.

4. *Limacina.*—This genus is nearly allied to Clio, in the form of the head and wings, but the body of the animal is contained in a tender shell of one turn and a half, flat on one side, with a large umbilicus in the other. When the animal swims, the head and fin-like expansions are protruded from the shell.

This genus was instituted by Cuvier, for the reception of the Clio helicina, an animal first described by Captain Phipps, and afterwards by Fabricius, under the name of Argonauta artica. According to Mr. Scoresby, it is found in immense quantities near the coast of Spitzbergen, but does not occur out of sight of land.

5. *Pneumodermon.*—The body, in the species of this genus, is oval. The neck is narrow, with a fin-like expansion on each side. The mouth is nearly terminal, furnished on each side with a fleshy lip, and below with a fleshy chin. On the summit are two bundles of tentacula, each consisting of a filament, with a tubercle at the end, pierced by a small hole, and considered as exercising the office of a sucker. Cuvier, in his *Memoire sur L'Hayle et le Pneumoderme*, considered the leaf-like ridges which occur on the caudal extremity of the body as the branchiæ, and even describes the pulmonary vein which conveys the blood from these to the heart. But, in his *Regne Animal*, he states it as the opinion of his assistant, M. Blainville, that the fin-like expansions of the neck contain the branchiæ on their surface, as in the case of Clio. The rectum and oviduct terminate under the right wing. Cuvier has figured and described the only known species, which he terms *Pneumodermon Peronii*, the trivial name being in honour of the discoverer, M. Peron.

6. *Hyalea.*—The animals of this genus, as we have already stated, are destitute of a head. The body is lodged between two plates or valves, united at the base, where they inclose the caudal extremity. The ventral valve is nearly flat, with an uneven margin, narrow anteriorly, but expanding behind, and terminating in three projecting points. From the middle point four ribs diverge forward, and a muscle arises, which, fixed in the superior viscera, enables the animal to withdraw into the shell. The dorsal valve is shorter than the preceding, the margin flat and circular, and the middle convex outwardly. In the space between the lateral margin of the two valves, on each side, the branchiæ are situated, in a duplicature of the tunic, the sides of which are furnished with filaments. The fleshy neck supports the two membranaceous expansions; between which and the base the mouth is situated, surrounded by two lips, and strengthened within by two fleshy cheeks. The opening of the anus and oviduct are at the base of the right fin.

The Hyalea tridentata, the best known species of the genus, was first noticed by Forskal, in his *Descriptiones Animalium*, p. 124, as an Anomia, and inhabiting the Mediterranean.

Class III.—GASTEROPODA.

The animals which are included in this class are more numerous in regard to species, and exhibit a greater diversity of organization, than those belonging to the other great divisions of molluscous animals. They have long occupied the attention of the zoologist, and various methods have been proposed for their artificial and natural arrangement. Their internal structure has likewise been investigated with a considerable degree of success, and the purposes which the different organs serve in the animal economy, have been in a great measure ascertained.

The Gasteropoda present few characters which are common to the whole class. Their body may be regarded as consisting of a foot, the cloak or tunic, and the head. The *foot* is a firm muscular expansion, covering a part or the whole of the ventral surface of the animal. The viscera and head rests on its central surface, while externally it exhibits a soft even disk, capable of acting as a sucker, with which the animal adheres to objects when at rest, and by which it crawls from one place to another. It is likewise used as a fin in swimming, being aided at the same time by the serpentine motion of the whole body. The tunic arises on each side of the foot, and forms an arch over it for the reception of the viscera. Behind, the sac thus formed is closed, whose front is occupied by the neck and head. The tunic on the back is, in some cases, fortified by one or more testaceous plates; in others it is protected by a conical or spiral shell.

The *head* is connected at the sides and on the back with the cloak, and beneath with the foot. In general it is furnished with tentacula as organs of touch.

The organs of circulation are more simple than in the cephalopoda. There is no pulmonic auricle nor ventricle, the veins which correspond with the vena cava in the higher classes proceeding directly to the lungs or branchiæ. There is, however, a systemic auricle, which receives the aërated blood, and a systemic ventricle, which transmits it to the different parts of the body. The heart is usually situated on the left side; but in those genera furnished with a spiral shell, it is always on the side next the pillar, or the one opposite to that to which the spire of the shell is directed.

The organs of respiration exhibit the two modifications of lungs and gills. The lungs, destined to respire free air, are usually seated in a cavity on one side, whose orifice is capable of being closed at the will of the animal. The walls of this cavity are lined with a delicate net-work of vessels, in which the blood is exposed to the decarbonizing influence of the atmosphere. In those animals whose blood is aërated in water, the gills exhibit every variety of form. In some they occur in a cavity, or exposed in the form of pectinated ridges, in others assuming the appearance of shrubs. In all cases these organs are well protected, delicate in structure, and exceedingly sensible to any external impression.

These two conditions in the organs of respiration point out the propriety of forming the Gasteropoda into two subdivisions, which may be termed, according as they respire by means of lungs or gills, *Pulmonifera* and *Branchifera*. Cuvier appears to have been in some measure aware of the importance of the distinction, when he instituted his order *Pulmonés*. But he afterwards suffered himself to be more influenced by the presence of an operculum, the shape of the aperture of the shell, and the supposed separation of the sexes, than by the characters of the respiratory organs. Hence he inserted the pulmoniferous genus Cyclostoma among those which are furnished with gills.

Subdivision I.—Gasteropoda Pulmonifera.

The distinguishing character of this group of Gasteropodous mollusca, is to respire free air. This is performed in a pulmonary cavity situated at the side, the entrance to which the animal is capable of closing at pleasure. The blood-vessels are spread upon the walls of this cavity, chiefly on the roof, in the form of a delicate net-work. The opening of the cavity is usually on the right side, with the anus behind it, and the sexual orifice is in the front near the head. In some of the genera these openings are situated on the left side. The shells of the former are denominated dextral—of the latter sinistral. This change in the position of the external openings is accompanied by corresponding alteration in the arrangement of the internal organs. The heart, for example, is always placed on the side opposite the pulmonary cavity. In the dextral shells, therefore, it is sinistral, while in the sinistral shells it is dextral. In both kinds, however, all the organs preserve the same relation to the back and belly, the head and tail. It is impossible, therefore, to conceive a dextral animal changed into a sinistral, by any circumstance which could take place at the period of hatching, as M. Bosc was inclined to believe. This arrangement of the organs must have been not merely congenital, but coeval with the formation of the embryo. In some species all the individuals are sinistral, while in others the occurrence is rarely met with in a solitary example. The former are in their natural state, the latter ought to be regarded as monsters. Where the character is permanent, it should constitute a generical difference.

The animals of this subdivision have, in general, the sexual organs united in the same individual, requiring, however, mutual union. They are all oviparous.

Section I.

This is intended to include all those pulmoniferous gasteropoda which are *terrestrial*. These reside constantly on the land where they have been hatched, and where they collect their food and propagate their kind. They admit of division into two tribes, from the circumstance, that in some the shell, which is either flat, or open and subspiral, is concealed in a thickened plate of the cloak, termed the *shield*, while in others the shell is spiral or conical, external, and contains the body of the animal.

Tribe I.—The genera included in this tribe are three in number. They all possess four tentacula, capable of being withdrawn into themselves like the fingers of a glove. The eyes are black points, seated at the tips of the superior tentacula.

I. Limax. *Slug*.—The body is lengthened, and somewhat pointed behind. The cloak is corrugated, and supports the shield on the forepart of the back towards the head, containing a thin corneous or testaceous plate. The pulmonary cavity opens on the right side, at the inferior margin of the shield. Behind this opening is the anus. The sexual opening is underneath the superior tentaculum, on the right side. At the termination of the body, above, is an opening, out of which a thick glutinous fluid oozes. The surface of the whole body is liberally supplied with a glutinous secretion of the same sort, but thinner in its consistence. This fluid issues from the pores of the skin and the pulmonary cavity, and when the animal is placed before the fire, it is given out in considerable quantities. The respectable editors of the *Journal d'Histoire Naturelle*, vol. i. p. 477, recommended a lute made of this fluid, reduced to a proper consistence by quicklime, for the purpose of securing the mouths of the bottles containing anatomical preparations, and preventing the evaporation of the alcohol. With this cutaneous secretion some of the species are capable of forming a thread, by which they are able to suspend themselves from the branches of trees. This mode of assisting locomotion is recorded by Lister, (*Animalium Angliæ*, p. 130.) and subsequently noticed by other observers. *Linn. Trans.* vol. i. p. 182; and vol. iv. p. 85.

The mouth consists of lips, which are capable of small extension, and above, the entrance is armed with a concave corneous jaw, with a notch in the middle. The tongue is merely armed with soft transverse ridges, pointed before, and terminated by a short cartilaginous cone. There is a sensible dilatation of the gullet, which marks the place of the stomach, at the under extremity of which is the rudiment of a cæcum at the pyloric opening. The intestine makes several folds, chiefly in the liver, before it reaches the anus. The salivary glands reach to the extremity of the gullet. The liver is divided into five lobes, which gives rise to two ducts that open into the pylorus.

The circulating system consists of two venæ cavæ, which give out numerous branches to the pulmonary cavity. The aërated blood is conveyed by several ducts to a simple membranaceous systemic auricle. Between the auricle and ventricle there are are two valves. The ventricle is more muscular than the auricle. The arteries, which take their rise from a single aorta, are characterised by a peculiar opacity and whiteness of colour, as if they were filled with milk.

The organ of viscosity nearly encircles the pericardium. It consists of regularly pictinated plates. Its excretory canal terminates at the pulmonary cavity.

The organs of generation consist, in the female parts, of an ovarium, oviduct, and uterus; and in the male, of a testicle, vas deferens, and penis, together with the pedunculated vesicle; and, as common to both the sexual organs, there is a cavity opening externally, in which, by separate orifices, the uterus, penis, and vesicle terminate.

The species of this genus have hitherto been chiefly characterised by the shape and colours of the body; the latter, however, is liable to such great variation, that it is difficult to determine the number of species which are natives of Britain. The structure of the shield, and the relative position of the pulmonary cavity, joined with the markings of the body, ought to be resorted to; and could a knowledge of the internal structure be likewise obtained, we might then hope to be able to bestow on the species permanent marks of distinction.

Although the terrestrial gasteropoda may be considered as phytivorous, it is now known that the larger species of this genus likewise feed on the common earthworm, as has been observed by Mr. Power, (*Linn. Trans.* vol. ix. p. 323.) None of these species are used in this country as food.

II. Parmacella.—The animals of this genus are distinguished by the position of the shield, which is placed on the back, near the middle of the body, and contains, at its caudal extremity, an open subspiral testaceous plate. Underneath the shield is the pulmonary cavity.

The only species of this genus yet known was found by M. Olivier in Mesopotamia. The genus was instituted by M. Cuvier, and the species denominated P. olivieri. Along the back, from the shield to the head, are three grooves; the medial one is double. From the dissections of Cuvier, it appears that the internal structure of this species bears a close resemblance to that of the slugs. The most remarkable difference is in the two conical appendages of the common sexual cavity, by which they approach the Helices.

III. Testacella.—The shield in this genus is placed on the posterior extremity of the body, and consequently the anus and pulmonary cavity are nearly terminal. These are protected by an open subspiral testaceous plate. The foot extends on each side beyond the body. From the manner in which the blood is aërated, the auricle and ventricle are placed longitudinally, the latter being anterior.

The T. haleotoidea, described and figured in the *Histoire Naturelle des Mollusques Terrestres et Fluviatiles de la France*, par M. Draparnaud, p. 121. tab. xi. figs. 12—14, is the only species which has been distinctly ascertained. It lives in the soil, and pursues and feeds on the common earth-worm.

Tribe II.—The animals of this tribe were formerly included in the genera Helix and Turbo of Linnæus. The shells are spiral, and more or less turbinated. They are covered with a cuticle, which, in some cases, appears in the form of ridges or hairs. The following genera have been established:

1. Helix. *Snail.*—In this genus the animals have four tentacula, as in the Limax, with eyes at the tips of the superior ones. The aperture of the shell, which is somewhat lunulated, is as wide as it is long.

The internal structure of the snails very nearly resembles that of the slugs. The shield, however, has a thickened margin in front, by which the shell is formed, and the centre of the shield is as it were ruptured, giving vent to the liver and organs of generation. These occupy the cavity of the shell towards its tip, and the mouth is filled with the foot, body, and head. The animal is attached to the pillar of the shell by a complicated muscle, which shifts its place with the growth of the animal. The mouth is furnished above with a thin arched corneous mandible, notched on the edges.

The circumstances in which the snails differ from the slugs, are chiefly observable in the organs of generation. The vagina, previous to entering the common sexual cavity, is joined by the canal of the vesicle, and by two canals, each proceeding from a bundle of multifid vesicles. Each bundle consists of a stem, which is the canal, and numerous branches with blunt terminations. These canals pour forth a thin milky fluid, whose use is unknown.

Connected with the sexual cavity is the bag in which the darts are produced. The bag itself is muscular, with longitudinal grooves, and a glandular body at the extremity. This glandular body secretes the dart.

which is in the form of a lengthened pyramid, consisting of calcareous filaments nearly resembling asbestus. Previous to the sexual union, the two snails touch each other repeatedly with the mouth and tentacula, and at last the dart of the one is pushed forth by its muscular bag, and directed against the body of the other, into which it enters, never penetrating through the integuments, and even in many cases falling short of its mark. Whether the use of the dart is merely to stimulate, or whether it is subservient to any other purpose, can scarcely be said to be determined.

The species of this genus are numerous, and may admit of distribution into several sections, from circumstances connected with the form of the shell. Without instituting these at present, we shall subjoin a list of the species indigenous to Britain, which belong to this restricted genus :—1. H. Pomatia ; 2. virgata ; 3. cingenda ; 4. rufescens ; 5. cantiana ; 6. hispida ; 7. lucida ; 8. trochiformis ; 9. spinulosa ; 10. caperata ; 11. radiata ; 12. umbilicata ; 13. lapicida ; 14. albella (of Draparnaud,) found near St. Andrew's by Mrs. Fleming, Flisk ; 15. ericetorum ; 16. paludosa ; 17. crystallina (of Draparnaud,) found at Battersea by Dr. Leach ; 18. aspersa ; 19. memoralis ; 20. arbustorum ; 21. fusca ; 22. elegans (of Draparnaud,) the Trochus terristris of British writers.

The *Scarabes* of Montfort is formed from the Helix scarabæus of Linnæus.

II. Bulimus.—The shell furnishes the distinguishing mark in this family. It is turreted, and the mouth is longer than it is broad. The following species are indigenous : 1. lubricus ; 2. obscurus ; 3. lackhamensis ; 4. fasciatus.

The species which are related to the Turbo *bidens perversus* and *muscorum* of Linnæus, constitute a very natural family, which may be termed Pupacea, distinguished by the mouth being in general furnished with teeth, or testaceous laminæ, and the last whorl nearly the same or less than the preceding. Perhaps the most convenient way of dividing them is into two sections, the first including the dextral, and the second the sinistral shells.

The dextral pupacea form three genera. The Pupa, as originally constructed by Lamarck, was equally faulty with many of the old Linnæan genera. As we have restricted it to include dextral shells, with the animal possessing four tentacula, with eyes at the tips of the two longest, we can receive into it the *muscorum*, *sexdentatus*, and *juniperi*, of Montagu. The genus Chondrus of Cuvier contains the tridens of Montagu. In the genus Carychium, formed by Muller, the tentacula are only two in number, with the eyes placed at the base. It is represented by the T. *carychium* of Montagu.

The sinistral pupacea form two genera. The first, which is the Clausilia of Draparnaud, contains sinistral shells, with the animal furnished with four tentacula, with eyes at the tips of the two longest. To the pillar there is attached internally a twisted plate. This contains the following British species,—*perversa*, *nigricans laminata biblicata*, and *labiata*. The other genus, called Vertigo, was formed by Muller. The animal possesses only two tentacula, with the eyes on their tips. The T. *vertigo* is the type of the genus.

In the shells of the preceding genera, the margin of the mouth is always thick, and strengthened by a ring when the animal is arrived at full growth, after which the shell is stationary in point of size. This is a character peculiar to the terrestrial testacea. In the two genera which follow, the margin of the mouth is simple.

VIII. Vitrina.—This genus was formed by M. Daudebard de Ferussac, and termed by him Helico-limax. Draparnaud, to avoid the use of a hybrid name, substituted Vitrina. The shell is incapable of containing the animal. The margin of the shield is double, and the upper fold is divided into several lobes, which are reflected on the surface of the shell. The Helix pellucida of Muller is the type of the genus.

IX. Succinea. From the Helix succinea of Muller (the putris of Montagu and Donovan, not of Linnæus) Draparnaud has formed the genus Succinea. The mouth is large in proportion to the size of the shell, and effuse at the base, with the outer lip thin, and the pillar attenuated. We are at a loss to account for the conduct of Lamarck in substituting a new name for this genus without any apparent reason, and thus adding to the synonimes with which the science is already oppressed. The name first employed by Draparnaud, indicates one of the most striking characters of the type of the genus, whereas the term Amphibulina, used by Lamarck, is founded on a mistake, and is apt to mislead. The Helix succinea, although found in damp places, is not amphibious. It never enters the water voluntarily. Indeed, Muller says, " Sponte in aquam descendere nunquam vidi, e contra quoties eum aquæ immisi, confestim egrediebatur." The same remark is made by Montagu, and we have often witnessed its truth.

X. Achatina.—The mouth of the shell in this genus nearly resembles the Bulimi, but the end of the pillar is truncated. The Buccinum acicula of Muller, a native of England, belongs to this genus, and likewise the Helix octona of Linnæus, erroneously considered as a native of Britain.

XI. Cyclostoma. This genus is readily distinguished from all the preceding by the circular aperture of the shell, and the foot of the animal being furnished with a lid or operculum. This genus may be regarded as the type of a singular tribe of the terrestrial pulmonifera. The pulmonary cavity opens upon the neck, as in many of the pectinibranchia. The sexes are likewise separate, the penis of the male being large and muscular, but contained in the interior. The primary tentacula have sub-globular highly polished extremities, which Montagu (*Testacea Britannica*, p. 345.) is disposed to regard as eyes. The true eyes are placed at the base of the tentacula on the outside, and are elevated on tubercles, the rudiments of the second pair. The tentacula, though somewhat contractile, are incapable of being withdrawn, after the manner of the slugs and snails. The C. elegans, the Turbo elegans, of Montagu, is the type of the genus.

Sect. II.

The aquatic pulmoniferous gasteropoda, which are included in this section, have all two tentacula, usually flattened with the eyes at the internal base. The sexes are united. The spawn in the form of a gelatinous mass is deposited on aquatic plants, under water. The food consists of aquatic plants. Although they reside in the water, they are obliged to come to the surface to respire, when they open the pulmonary cavity, and, after remaining a short time, again close it and descend. Like the genera of the preceding section, they admit of distribution into two tribes.

Tribe 1.—This contains those animals which are naked, and which have been included in the genus *Onchidium*. In this genus, the animals are furnished with a cloak of more than ordinary thickness, which covers the whole of the upper part of the body. There are two long tentacula on the head, capable of being withdrawn like those of the slug. The snout is divided into two broad appendages. Between the tentacula, towards the right side, is the opening for the penis. The anus is terminal, above which is the entrance to the pulmonary cavity, and on the right is the opening to the female organs, from which a groove runs towards the right lobe of the snout.

The mouth is destitute of proboscis or jaws. The tongue is merely a cartilaginous plate, grooved transversely. The gullet is long in proportion, with a villous surface. There are three stomachs, each distinguished by its peculiar characters. The first is a true gizzard, covered internally with a cartilaginous cuticle, and its walls formed of two strong muscles with connecting ligaments. The second stomach is funnel-shaped, with prominent ridges, both on its external and internal surface. These ridges at their origin, internally, are highest, and project considerably into the cavity, acting like a valve in retarding the progress of the food. The third stomach is short and cylindrical, covered internally with equal longitudinal fine ridges. The intestine is nearly of equal thickness throughout, and about two and a half times longer than the body. The salivary glands are much branched, and pour their contents into the entrance of the gullet. The liver in the animals of this genus is distributed into three separate portions, each of which may be regarded as a distinct liver, an arrangement which is not known to take place in any other animal. The first liver is situated near the middle of the body on the right side, while the second is situated near the posterior extremity. The ducts enter the cardiac opening of the stomach, each by a separate hole, and seem to occupy the place of the zone of gastric glands observed in birds. The third liver is placed at the posterior end of the gizzard, into which it pours its contents by a short duct.

The most remarkable feature of the circulating system, is the position of the lungs, at the posterior extremity of the body, which occasions a corresponding arrangement in the connecting organs. The entrance to the pulmonary cavity is immediately above the anus. The vessels in which the blood is aerated are distributed on the roof and sides of the cavity. The pulmonic veins consist of two receptacles, one on each side, extending nearly the length of the body, which may be considered as venæ cavæ. These receive the blood by numerous vessels, and convey it directly to the lungs. The aërated blood is conveyed by a systemic vein into a large auricle, seated in front of the lungs, of considerable size, with the walls fortified on the interior by branched ligaments. The ventricle is placed at its anterior extremity, and separated by two valves. The aorta arises from the opposite side of the ventricle, its main trunk passing on towards the head.

The male and female organs of generation, although occurring in the same individual, appear to occupy different parts of the body. The opening of the male organs is at the tentacula, which leads to a cavity terminating in two unequal recesses. The anterior is the smallest, and receives the termination of a vessel three or four times longer than the body itself, which takes its rise at the external base of the cavity itself, apparently from the cellular substance, and, after a variety of convolutions in the neighbourhood of the mouth, opens into the recess. The second recess is the largest, and the vessel connected with it is more complicated. Its origin is in a mass, which occupies a considerable portion of the abdominal cavity, and which consists of a vessel forming a great number of complicated convolutions, liberally supplied with blood vessels. The duct which proceeds from this mass suffers a sudden thickening of its walls for a short space, after which it again contracts, and before it terminates in the recess, in a perforated glandular knob, it contains a pedunculated fleshy body with a sharp-pointed corneous extremity, probably capable of being protruded into the recess and cavity.

The parts which are considered as forming the female organs, or which are connected with the sexual cavity on the right side of the anus, consist of an ovarium divided into two lobes, each of which may be perceived to be again minutely subdivided. The oviduct is tortuous, and passes through a glandular body, which in the other gasteropoda is regarded as the testicle. The pedunculated vesicle gives out two ducts, one of which goes to the testicle, the other to the uterus. It is difficult to form even a conjecture regarding the uses of all this complicated sexual apparatus. The subject can only be elucidated by an attentive examination of the condition of the organs at different seasons of the year, and studying at the same time the habits of the animals.

The preceding description of the characters of the genus is taken from the anatomical details of Onchidium peronii, a species found creeping upon the rock under water in the Mauritius, by M. Peron. The genus was first instituted by Dr. Buchanan in the *Linnean Transactions*, vol. v. p. 132, for the reception of a species which he found in Bengal, on the leaves of Typha elephantina. This species, however, if the description be accurate, differs essentially from the one described by Cuvier, and would lead us to infer that a new genus would be necessary for the reception of the species of the last mentioned naturalist. "This is not, (says Dr. Buchanan,) like many others of the worm kind, an hermaphrodite animal, for the male and female organs of generation are in distinct individuals. I have not yet perceived any mark to distinguish the sexes while they are in copulation, as, in both, the anus and sexual organs are placed in a perforation (*cloaca communis*) in the under part of the tail, immediately behind the foot; but during coition the distinction of sexes is very evident, the penis protruding to a great length, considering the size of the animal." Cuvier seems disposed to suspect the accuracy of these sentiments, and as they do not appear to have been the result of dissection, it would be desirable to have the doubts on the subject cleared up by a re-examination of the animal in question. Dr. Buchanan is probably correct in considering the tentacula as occillated.

Tribe II.—In this tribe the animals are furnished with a distinct external testaceous covering. The species which it includes were dispersed by Linnæus, through the genera Helix, Bulla, Voluta, and Patella, according to the characters furnished by the shell. They are now arranged under the following genera.

1. Lymnæus.—The shells of all the species are dextral. The animal is constructed so nearly on the plan of the snail, that it will be unnecessary to enter into any details of its structure, farther than to take notice of the more remarkable peculiarities. The tentacula are two

in number, lanceolate and depressed, and incapable of being withdrawn. The eyes are seated on the head, at the inner base, and a little in front of the tentacula. The mouth is furnished with three jaws, the two lateral ones simple, the upper one like the slug, crescent-shaped, with a notch in the middle. The male and female organs, though intimately connected, internally, have their external orifices separated to a considerable distance, the former issuing as usual under the right tentaculum, the latter occurring in a cavity near the the pulmonary opening on the side under the border of the cloak. In consequence of this arrangement, the individuals of *L. stagnalis* have been observed by Geoffroy and Muller to unite together in a chain during coition, the first and last members of the series exercising only one of the sexual functions, the intervening individuals impregnating and receiving impregnation at the same time. Whether this is the constant or only accidental practice of this species, does not appear to be determined. We know that many other species of the genus are mutually impregnated as usual in pairs only.

The species of this genus are numerous. They reside in pools, lakes, and rivers. They furnish a favourite repast to the different kinds of trouts and water-fowl. The following are natives of Britain. L. stagnalis, fragilis, palustris, fossarius, octanfractus, detritus, auricularius, putris, glutinosus, and probably Helix lutea, of Montagu.

With regard to the Lymneus auricularius, it would appear, from the observations of Draparnaud, "*Histoire des Mollusques*," p. 49, that it exhibits a very singular structure of the respiratory organs. We shall quote his own words. "L'animal est pourvu de quatre filamens ou tubes qui partent de la partie supériure du cou, près du manteau; ce sont des trachées. Ces tubes sont longs, blancs et tres-transparens, et on ne les distingue bien qu'a la loupe. Leur surface est comme rugueuse, et leur extrémité est un peu renflée. Ils sont rétractiles. L'animal les fait sortir à volonté, un, deux, trois ensemble: il les agite et les contourne sans cesse en divers sens: ce qui fait qu'on les prendroit pour de petits vers. Je présume que par ce mouvement ces organes séparent de l'eau l'air que y'est contenu et l'absorbent. Cet animal est très sujet, ainsi que les autres gasteropodes fluviatiles, à être infesté par le *nais vermicularis* qui se loge ordinairement entre le cou et le manteau, au dessous des tentacules, et s'agite sans cesse d'un mouvement vermiculaire." Little doubt, we think, can be entertained that this naturalist had been deceived by some of the parasitical leeches which infest the aquatic pulmonifera, and that, instead of breathing by means of tubular gills, the animal of the L. auricularius possesses, like those which it resembles in other characters, a pulmonary cavity.

II. Physa.—The shell of the animals of this genus nearly resembles that of the preceding, with these differences, however, that the whorls are sinistral, and the pillar lip is destitute of a fold. The external appearance of the animal is similar to Lymneus, but the margin of the cloak is loose, divided into lobes, and capable of being reflected over the surface of the shell near the mouth. The *Bulla fontinalis* of British conchologists, is regarded as the type of the genus which was instituted by Draparnaud.

III. Aplexa.—The shell of this genus is likewise sinistral, but it is more produced than the former, and possesses a fold on the pillar lip. The cloak of the animal is incapable of being reflected upon the shell, and its margin is destitute of lobes. This genus (from α and πλεξις, *lacinia*) has been instituted for the reception of the Bulla *hypnorum* and *rivalis* of British authors.

IV. Conovula.—This genus was instituted by Lamarck, for the reception of several species of fluviatile *volutæ*, as the *auris-midæ*. The shape of the shell is conical, the spire forming the base. The pillar is furnished with ridges. The form of the inhabitant is unknown.

V. Planorbis.—Independent of the character derived from the spires of the shell revolving in nearly the same horizontal plane, the animal is furnished with tentacula, which, unlike those of the preceding genera, are long and filiform, with the eyes, however, placed as usual on their internal base. It is a sinistral genus, the anus, pulmonary cavity, and sexual organs, being on the left, and the heart on the right side. Some of the species, particularly *P. corneus*, pour forth, when irritated, a purple fluid from the sides, between the foot and the margin of the cloak. In internal structure, the animals of this genus resemble those of the genus Lymneus. The British species are nine in number, and reside in shallow ponds and ditches, among aquatic plants, on which they feed.

VI. Segmentina.—We instituted this genus several years ago, for the reception of the *Nautilus lacustris* of Lightfoot, first described and figured in *Phil. Trans.* vol. lxxvi. p. 160. tab. i. fig. 1—8. The shell externally bears a close resemblance to a Planorbis, but, internally, it is divided into distinct chambers by solid transverse septa, which communicate with each other by a triradiated aperture. The animal possesses the same filiform tentacula with the eyes at their base, which distinguish the species of Planorbis, but it is uncertain whether the openings on the side be dextral or sinistral.

VII. Ancylus.—The shell in this genus is a short compressed cone, nearly resembling the commen Limpet. The tentacula are short, compressed, a little truncated, with eyes at the internal base. The foot is short and elliptical. This genus was instituted by Geoffroy, and includes the *Patella lacustris* and *oblonga* of British writers.

Subdivision II.—Gasteropoda Branchifera.

The animals of this subdivision are chiefly inhabitants of the ocean a few, however, are found in fresh water lakes and streams. They admit of distribution into the following orders.

I. Order. *Nudibranchia.*

This order chiefly contains those animals which Linnæus included in his genus Doris. Since the writings of the illustrious Swede, many new species have been discovered, rendering the construction of several new genera necessary.

All the animals of this order are destitute of a shell or corneous plate on the back.* The head is furnished with tentacula. The branchiæ are external, and consist of simple or compound filaments arising from the cloak on the sides or back. In many species, the back is covered with perforated papillæ, which probably give rise to a mucous secretion. All the species are hermaphrodite, with reciprocal impregnation. The external opening of generation is situated at the right side. In two genera, Doris and Polycera, the anus is situated on the back, and surrounded by a disk fringed by the branchiæ. In the other genera the anus is situated on the right side.

I. Doris.—This genus, as now restricted, contains such animals as have the anus on the back towards the tail, surrounded only with a fringe of plumose branchiæ. The cloak is more or less covered with papillæ, which the animal has the power of contracting at pleasure. It is divided from the foot by a distinct duplicature. Towards the anterior margin are the two superior tentacula, which are likewise retractile. Each, at the base, is surrounded with a short sheath, supported on a slender stem, with an enlarged compound plicated summit. The neck is short, and above the mouth is a small projecting membrane, connected at each side with the inferior tentacula. These tentacula are in general small, and in some cases it is difficult to detect them.

The mouth is in the form of a short trunk, leading to fleshy lips, within which the tongue is placed. It is covered with minute reflected hairs, and, from its motion, appears to be destined exclusively for deglutition. The gullet is a simple membraneous tube, terminating in a stomach presenting on the interior a few longitudinal folds. It is furnished with a small cæcum, whose extremity receives the bile from the liver. The stomach likewise receives the secretion of another gland, which is not connected with the liver. It is in the form of a small bag, whose inner surface is covered with numerous papillæ. The intestine is lodged in a groove on the surface of the liver, and proceeds directly to the anus.

The liver itself is divided into two lobes, and gives rise to numerous biliary ducts, which proceed to the stomach. But it likewise gives rise to a duct which proceeds to a small bag plaited on the inside, and afterwards opens on the surface at a small hole near the anus. It yet remains to be determined, whether the fluid carried off by this conduit be excrementitious matter, separated by the liver, or whether the gland which produces it be distinct from that organ, but so interwoven therewith as to elude the observation of the anatomist.

It is obvious, from the structure of the digestive organs, that the species subsist on soft food, requiring neither cutting nor grinding, and in this respect differ remarkably from the species of the genus Tritonia, which were formerly arranged along with them.

The organs of generation differ little from the other hermaphrodite gasteropoda. The vesicle furnishes two canals, one of which goes to the testicle, the other to the penis. There is likewise a minute bag connected with the canal of the latter. They deposit their spawn on sea-weeds and stones. It is gelatinous, of a white colour, and in appearance resembles the Spongia compressa.

The species of this genus are numerous, although their specific characters are still imperfectly ascertained. The following species have been detected in the British seas.

1. *Doris argo.*—Body about three inches in length, nearly smooth, and of a lemon-yellow colour. The anal plumes about twelve in number. It is called sea-lemon. Pennant's *Brit Zool.* iv. p. 43. tab. 22.

This species is not uncommon in the crevices of the rocks about low-water-mark.

2. *Doris verrucosa.*—Body about one inch in length, the cloak closely covered with tubercles; superior tentacula, smooth at the base, compressed at the summit. The vent surrounded with about twenty-four plumes.

The species which Cuvier has figured under this name, *Mem. sur le Genre Doris*, tab. 1. fig. 4, 5, 6, 7. is represented as having only sixteen anal plumes. Equally common with the preceding in the same situation. Frequently cast ashore after storms.

3. *Doris lævis.*—Body about half an inch in length, and widest in front. Foot narrow. Cloak smooth in the middle, tuberculated slightly towards the margin. The vent surrounded with eight plumes.

This species is figured by Muller, *Zool. Dan.* tab. 47. fig. 3, 4, 5. It is very common in company with the former among the Zetland isles.

4. *Doris marginata.*—Length about a quarter of an inch. Cloak smooth, tinged with pink, with an undulated membraneous border, usually four-pointed in front.

This species occurs on the coast of Devon, where it was observed by the late George Montagu, Esq. by whom it was described and figured in the *Linn. Trans.* vol. vii. p. 79. tab. vii. fig. 7 He refers to the figure D. lævis in the *Zoologia Danica* as synonimous, but with doubt. We have no hesitation, however, in considering them as distinct. The D. electrina of Pennant is, however, probably a variety, but the brevity of the description and imperfection of the figure which he has given render reference uncertain.

5. *Doris nodosa.*—Length about half an inch. Foot broad, emarginate in front. Cloak with four equidistant papillæ, on each side a mesial line. Plumes of the vent about nine in number.

This is another species discovered by Montagu, *Linn. Trans.* vol ix. p. 107. tab. vii. fig. 2.

6. *Doris quadricornis.*—Length about three-eighths of an inch. Cloak smooth in the middle, with a row of obsolete tubercles on each side. Tentacula approximated in pairs. Vent surrounded by eight or nine plumes.

This is a rare species, and is described and figured by Montagu, *Linn. Trans.* vol. xi. p. 17. tab. iv. fig. 4.; probably the type of a new genus.

7. *Doris nigricans.*—Length about half an inch. Cloak thickly covered with short lanceolate tubercles. Above the head emarginate. Sheath of the superior tentacula notched in the margin. Anal plumes about eight in number. Body pale, frecked with dusky.

We have found this species in the Zetland seas, and have not met with any description with which its characters correspond.

II. Polycera.—This genus is nearly allied to the former. It was instituted by Cuvier, for the reception of those species whose anus is surrounded with plumes, but which possess, in addition, two membranaceous plates wherewith to cover them. The superior tentacula are similar to those of the Doris, but the inferior ones, surrounding the mouth above, are more numerous, extending from four to six.

This genus contains fewer species than the preceding. Two, however, have been detected as natives of the British seas.

1. *Polycera flava.* Length about half an inch. Feelers above the mouth four in number; superior feelers two, awl-shaped. Anal plumes seven, behind which are two long smooth appendages.

This species is described and figured by Montagu, *Linn. Trans.* vol vii. p. 79. tab. vii. fig. 6. The figure exhibits two black dots behind the tentacula, probably intended for eyes, although no notice is taken of them in the description.

2. *Polycera pennigera.*—Length half an inch. Cloak pointed behind; contracted at the tentacula, and emarginate in front. Tentacula subclavated and perfoliated, with a sheath of two leaves. Anal plumes five, with two bifid appendages.

Described and figured by Montagu. *Linn. Trans.* xi. p. 17. tab. iv. fig. 5.

In those genera of this order, in which the anus is situated on the right side, and unconnected with the branchiæ, some, as the Tritonia and Scyllea, are furnished with corneous jaws, while in the thethys, there are only muscular lips. The mouth in the other genera has not been examined with sufficient attention. The presence of jaws, however, is an important addition to the digestive organs, enabling the animals to cut the substances on which they feed, while the others must swallow their food entire.

III. Tritonia.—This genus was instituted by Cuvier, for the reception of those animals formerly arranged under the genus Doris, which have the branchiæ disposed on each side the cloak. Many of the species possess eyes, or at least black points which are regarded as such. There are two superior tentacula, as in the Doris, which are in part retractile, and above the mouth sometimes another pair, or in their stead plumose appendages.

The mouth consists of two lips, which are placed longitudinally, and open into a short canal. Within are the jaws, which consist of two corneous plates united at the upper dorsal edge, slightly arched, and meeting at their upper margin, for the purpose of cutting. Within these is the tongue, which differs remarkably from the same member in the Doris. In the latter, the spines with which it is beset are reflected, and draw the food to the gullet, while in the former, the spines are deflected, and serve to keep the food within the reach of the jaws. The tongue of the Doris therefore serves for deglutition, that of the Tritonia for mastication. M. Cuvier, by mistake, describes the functions of both as similar. The salivary glands are placed on each side the gullet, and empty their contents behind the jaws. The gullet has a few longitudinal folds, the stomach is simple, scarcely different from the gullet, and the intestine proceeds almost directly to the anus, situated on the right side. The liver is small and situated behind, enveloping the stomach, and intimately united with the ovarium. The organs of generation exhibit nothing remarkable. The pedunculated vesicle has a simple canal. The external opening of the organs of generation is situated a little before and beneath the anus.

The following species are natives of the British seas:

1. *Tritonia arborescens.* Length about an inch. Margin above the mouth, with four plumose appendages. Foot narrow, sides compressed. Cloak smooth, soft, with five or six plumose tubercles on each side, decreasing in size towards the tail. Tentacula two, feathered, contained in a sheath.

This species is described and figured by Cuvier, in his *Memoire sur la Scyllée*, p. 27. tab. 1. fig. 8, 9, 10. We have found this species in the Zetland isles, agreeing with the characters of Cuvier, with this difference, that the branchiæ in his are only five, while in ours they appeared to be six on each side. But as the two posterior ones are very small, and as his examples were preserved in spirits, it is probable that they have escaped detection.

2. *Tritonia pinnatifida.* Length three-tenths of an inch. Tentacula filiform, inserted in a trumpet-shaped sheath. Branchiæ in a single row on each side, ovate, consisting of grey papillæ with black lips, arranged in five or six whorls.

First described and figured by Montagu, *Linn. Trans.* vol. vii. p. 78. tab. vii. fig. 2, 3.

3. *Tritonia bifida.* Length about a quarter of an inch. Tentacula (sheath?) two, broad, erect, and bifid, behind which are two eyes. Branchiæ in a single row, on each side, ovate, pedunculated, unequal; opposite pairs equal, summit semitransparent, uniform on the surface, but complicated within.

First observed by Montagu. *Linn. Trans.* vol. xi. p. 198. tab. xiv. fig. 3.

M. Cuvier has separated from the genus Tritonia such species as possess four tentacula; two superior, and two at the anterior extremity of the body. The branchiæ are placed in transverse rows along the sides and back. He likewise states, that there is no cloak, or rather no marked division between the cloak and the foot. This genus he has termed *Eolida.* Unfortunately none of the characters which are here selected, appear to mark any particular plan of organization; and the species to which he refers, differ as widely from one another as they do from the Tritoniæ. Three of his references are to British species, which we shall now describe. In all of these the branchiæ are simple, neither in the form of imbricated processes, nor plumes.

4. *Tritonia papillosa.* Length nearly three inches. Anterior tentacula smooth, superior ones annulated. Middle of the back smooth, sides thickly set with conical lengthened branchiæ, which, when closely examined, appear to be disposed obliquely in rows, containing about ten in each.

"From the points of the papillæ, (says Montagu,) an extremely viscid secretion is discharged, that sometimes envelopes the whole animal." We have observed it possess the horny jaws of a Tritonia.

This species is not uncommon at different parts of the coast. It was probably first observed as British by Turton, who appears to refer to it in his *British Fauna*, under the name Doris vermigera. It is described and figured by various authors, particularly by Baster. *Opuscula Subseciva*, i. p. 81. tab. x. fig. 1. A. B. C. D. Muller, *Zoologia Danica*, tab. cxlix. fig. 1, 2, 3, 4. Montagu, *Linn. Trans.* vol. xi. p. 16. tab. iv. fig. 3.

5. *Tritonia plumosa.* We have observed in Zetland this small species, which is about half an inch in length. It resembles the preceding in form, but has only one row of simple branchiæ on each side. The superior tentacula were pinnated towards the summit. The anterior ones simple. Opportunities for a more minute examination did not occur. The structure of the superior tentacula forbid us to regard it as the young of the T. papillosa.

6. *Tritonia cœrulea.* Length about a quarter of an inch. Tentacula simple, with eyes behind the superior pair. Branchiæ clavate in transverse rows on the back. Two oval vesicles on the right side, between the second and third row of branchiæ.

Described by Montagu, *Linn. Trans.* vol. vii. p. 78. tab. vii. fig. 4, 5.

7. *Tritonia longicornis.* Length half an inch. Ante-

rior tentacula about half the length of the body; the superior pair short, with the eyes behind. On the right side, near the eyes, a cluster of short papillæ. Branchiæ on the back in four transverse rows.

Described by Montagu, *Linn. Trans.* vol. ix. p. 107. tab. vii. fig. 1.

It is probable that the cirri on the right side, in this and the preceding species, mark the anus, and furnish a character for a generic distinction.

8. *Tritonia pedata.* Length about half an inch. The four tentacula subclavated and wrinkled, with eyes behind the superior pair. Branchiæ in four fasciculi, imperfectly connected transversely. Foot with two fleshy lobes in front.

This species is described by Montagu. *Linn. Trans.* vol. xi. p. 197. tab. xiv. fig. 2.

IV. Tergipes.—This genus was instituted by Cuvier, for the reception of those species which have only two tentacula, and a single row of branchiæ on each side, which act likewise as suckers, and enable the animal to crawl on the back. Forsthal described one species in his *Descriptiones Animalium*, p. 99, as Limax tergipes. The species may be distinguished by the number and form of the branchiæ.

1. *Tergipes maculata.* Length about a quarter of an inch. Tentacula filiform, retractile, with a trumpet-shaped sheath. Branchiæ nine on each, and consisting of a clavate sheath, with a sexpartite margin, a concave summit, with a single papilla in the centre.

Described by Montagu. *Linn. Trans.* vol. vii. p. 80. tab. vii. fig. 8, 9.

V. Thethys. This genus is characterised by a row of branchiæ on each side the back, and a large membranaceous expansion above the mouth, bearing two tentacula towards its base.

This genus was first instituted by Linnæus, but it is to M. Cuvier that we owe the discovery of its most important characters.

The body is ovate, with the cloak and foot continuous. The neck is distinct from the foot, and is narrow. Above, the neck is continuous with the cloak, from which arises a large semicircular expansion, which the animal probably uses as a fin. The margin of this expansion is fringed with numerous filaments, and on the upper surface, within the border, is a row of conical tubercles. The true tentacula are placed towards the base of this fin near the neck. They consist each of a small fleshy cone, striated across, with a semicircular sheath behind. The branchiæ consist of tapering fleshy stalk, spirally twisted towards the summit with a series of filaments on one side. They are fourteen in number on each side, alternately and oppositely small and large. The anus opens in front of the third branchia on the right side. The orifice of generation is exhibited under the first branchia of the same side. In the front of each of the larger branchiæ is a small cavity, with a small filament in the centre.

The mouth is situated underneath the tentacula. It consists of a large funnel, covered within with soft papillæ, destitute of jaws or tongue. The gullet is short, the stomach simple, fleshy, and covered with a thick cuticle. The salivary glands are slender and branched, and open into the gullet. The intestine is likewise short, and proceeds directly to the anus. The liver pours the bile into the canal at the pylorus; and likewise sends out another duct, which opens externally near the anus. The organs of generation are similar to the Doris.

The Thethys fimbria is the only species of the genus which has been satisfactorily ascertained.

VI. Scyllea. The distinguishing characters of this genus depend on the two tentacula, the mouth being furnished with jaws, and the back with membranaceous expansions, bearing on their upper surface the branchial papillæ.

The foot is very narrow, forming a groove on the under surface. The body is ovate, and compressed laterally. There are two expansions or crests on each side, and one at the tail. The branchiæ are in the form of plumes, covering the upper surface of the crests and the back. The tentacula are each contained within a large funnel-shaped sheath.

The mouth is placed at the base of the tentacula, surrounded with a semicircular lip. The jaws are horny, and cut by crossing each other. The tongue is furnished with reflected points. The gullet is longitudinally plaited. The stomach is short and cylindrical, with a ring of hard longitudinal scales. The liver consists of six unequal globules. The bile is poured into the cardiac extremity of the gullet.

The Scyllea pelagica has been long known to naturalists, and appears to be very common in the equatorial seas. It is commonly found adhering to the stems of the fucus natans.

VII. Glaucus. In this genus, whose true characters are still imperfectly explored, the head is furnished with four simple tentacula. On each side the body are three or four horizontal membranaceous expansions, whose margins are fringed with the branchial filaments.

This genus was instituted by R. Foster, and the species with which naturalists have been longest acquainted, is the Doris radiata of Gmelin, which is figured in the *Phil. Trans.* vol. lii. tab. iii. It is not uncommon in the Atlantic Ocean.

It is probable that a more minute examination of the animals of this order, than has hitherto taken place, would lead to the formation of several tribes and families. The number of the tentacula, the structure of the mouth, the connection between the cloak and the foot, the appendages of the anus, and the disposition of the branchiæ, lay claim to the notice of the systematical zoologist. But the study of these animals can only be carried on at the sea-shore, where they can be preserved alive in their native element.

II. Order. *Cyclobranchia.*

The animals of this order differ from the preceding in the marginal distribution of the branchiæ. Between the foot and the cloak, or dorsal covering of the body, the gills are placed, above the one, and beneath the other. These are in the form of little leaves, which constitute a fringed band on each side of the body; in some surrounding the whole body, in others interrupted front or behind. Independently of this remarkable position of the organs of respiration, M. Cuvier arranges the animals in which it occurs into two distinct orders, and places them far apart in his system. It is not easy to account for this distribution; as the only character of importance by which he has marked their separation, is derived from the circumstance, that, in the animals of his first order, the sexes, though united, require the mutual union of individuals, while, in the other, each individual is *supposed* to be capable of impregnating itself. In these last, however, the other organs, of feeling, digestion, or protection, have no common properties. Averse to any arbitrary arrangements of this kind, we have here brought them together under one order, and shall now proceed to consider the characters of the genera.

1. Phyllidia. The body, in the animals of this genus, is ovate. The foot is narrow in front. The cloak is broad, coriaceous, and destitute of a shell. Towards its anterior extremity are two cavities, from which issue the retractile superior tentacula, as in the genus Doris. Nearly at the posterior extremity is another cavity, containing the anus. This opening, though similar in situation to that of the Doris, is merely a short simple tube. The head is immediately above the anterior margin of the foot, above which is the mouth, having a small conical feeler on each side. Under the margin of the cloak on the right side, and about half way between the mouth and the middle of the body, are two openings, in a tubercle, for the organs of generation. The branchiæ consist of slender complicated leaves, which surround the body between the foot and the cloak. The circle is interrupted at the head and the tubercle of generation.

The mouth is destitute of jaws. The gullet is simple, ending in a membranaceous stomach. The pylorus is placed near the cardia, and the intestine goes directly to the anus. The salivary glands are small, and placed near the mouth. The liver is large in proportion.

The heart is placed in the middle of the back. The auricle is simple, placed on the side next the tail, and supplied by the two systemic veins which collect the aërated blood from the branchiæ on each side. There is a simple aorta arising from the opposite side of the heart.

The organs of generation appear to be similar to those of the preceding class; but they have not as yet been minutely examined. The existence of eyes is not satisfactorily determined.

The animals of this genus appear to be inhabitants of the tropical seas. Cuvier has given descriptions and figures of three species, which differ remarkably from one another in the protuberances of the cloak.

2. Diphyllida. This genus was formed by Cuvier in his *Regne Animal*, for the reception of an animal in the cabinet of M. Brugmans at Leyden. It is but imperfectly characterized. The cloak is pointed behind; the head semicircular, with a feeler, and small tubercle on each side. The anus is placed on the right side.

3. Patella.—*Limpet*. This genus differs from the others of this order, in being covered on the back by a conical shell, within the cavity of which the animal is capable of withdrawing itself. The cloak is large, covering both the head and foot. It is united with the shell along its superior margin. The foot is fleshy, and furnished with numerous muscular filaments, which unite in the superior part of the cloak, to form a strong muscle, by which the body adheres to the shell. The action of this muscle brings the shell close to the surface to which the foot adheres, or removes it to a distance.

The head is furnished with a large fleshy snout, supporting at the base two pointed tentacula. The eyes are placed on a small elevation at the external base of the tentacula. A little way behind the head, and below the cloak, on the right side, are two apertures, being the anus and orifice of generation. The gills occupy the same position as in the preceding genera. In some the branchiæ form a complete circle; in others the circle is interrupted anteriorly at the head.

Within the trunk, the mouth is fortified by two cartilaginous cheeks, which, at their union, anteriorly, support the base of the tongue. This last is a most singular organ. It is longer than the whole body, narrow, and covered with three rows of short reflected spines, interrupted longitudinally and transversely. Its fixed end only is exercised, its free end being coiled up the abdomen. On the upper side of the mouth is a semicircular osseous plate, or upper jaw. The gullet is furnished with a dilatable pharynx. The stomach is elliptical, with the cardia and pylorus at opposite extremities. The intestines are variously folded, and are several times longer than the body. The salivary glands are minute. The liver is intimately united with the stomach and intestines.

The heart is situated on the left side, in the anterior part of the body. The auricle receives the aërated blood from one vein when the circle of the gills is complete, and by two when interrupted. This auricle is placed on the anterior side of the heart. An aorta arises from each side, to convey the blood to the body.

The ovarium is placed underneath the liver; and as it exhibits some differences of organization, M. Cuvier infers that it likewise contains the male organs.

The species belonging to this group are numerous, and appear to admit of distribution into those having the branchial circle complete, and those in which it is interrupted.

4. Chiton. This genus is well characterised by a series of testaceous dorsal plates, and the absence of tentacula.

The body is elliptical. The cloak is firm and cartilaginous, and variously marked on the margin. The dorsal plates are arched, and occupy the middle and sides of the back. They are implanted in the cloak in an imbricated manner, the posterior margin of the first valve covering the anterior margin of the second. The foot is narrow. The mouth is surrounded with a semicircular curled membrane. The anus consists of a short tube, placed at the posterior extremity of the foot, which supplies the place of tentacula. The external orifice of generation has not been ascertained.

The mouth is capable of forming a short proboscis. The tongue is short, and armed with strong reflected spines. The gullet is short, and the stomach, which is lengthened and folded, is membranaceous. The intestine is several times longer than the body, and much folded. The liver is divided into numerous lobes, and intimately united with the stomach and intestines.

The heart is situated at the posterior part of the body. The auricle is placed posteriorly, and receives the aërated blood from two veins. Each vein descends along the base of the gills, collecting the aërated blood from the particular side of the body to which it belongs; and, what is most remarkable, when opposite the ventricle, it suffers an enlargement, and sends off a branch which communicates with it, and again contracts and unites with its fellow from the opposite side to form the auricle. A single aorta arises from the anterior side.

The ovarium is conical, and divided into numerous lobes. Behind, two ducts seem to arise, and to proceed one to each side; but it has not been determined whether they open externally. No male organs have been detected; nor is there any thing accurately known with regard to the peculiar nature of their hermaphroditism.

There are several species of chitons described in the article CONCHOLOGY as natives of the British shores. Even these furnish characters by which they may be distributed into groups. 1. Marginal band of the cloak, with tufts of spines, as the *C. fascicularis*. 2. Marginal band rough, as *C. marginatus ruber* and *cinereus*. 3. Marginal band striated, as *C. lævis* and *albus*. 4. Marginal band smooth, as *C. lævigatus*. The first ought to constitute a new genus apart.

The two first genera of this order, Phyllidia and Dephyllidia, are destitute of shells, and constitute the order Pleurobranchia of Cuvier. The two last, Patella and Chiton, are furnished with shells. They form the order Cyclobranchia of Cuvier. We have ventured to unite them under the latter denomination, being persuaded that the only character common to all of them is derived from the position of the gills, and that Patella and Chiton differ as much in the structure of their other organs from each other, as they do from either Phyllidia or Diphyllidia.

The only animal in this order which is valuable in an economical point of view, is the limpet. Although used by the ancients as an article of food, it is seldom brought to market in this country. The inhabitants along the coast, however, frequently use it as food when boiled; and its juice obtained by this means, when mixed with oatmeal, forms a dish known in Scotland by the name of *Limpet Brose*. It is in season about the month of May. It is much used as a bait in catching littoral fish.

ORDER III. *Tectibranchia*.

This order may be considered as represented by the genera Aplysia and Bulla of Linnæus. In many of the order Nudibranchia, the respiratory organs form a double row on each side the back. In the Cyclobranchia, the same organs occur on each side, but underneath the cloak. In the present order, the branchia occur underneath the cloak, but they are confined to a particular portion of the right side. They are all inhabitants of the sea. They exhibit the same hermaphroditism as the Nudibranchia. The order consists of the following genera.

1. PLEUROBRANCHUS.—This genus is particularly characterised by the foot and cloak forming two broad plates, which inclose the body. Between these, in the middle of the right side, the branchiæ are placed. The tentacula are two in number, with eyes at the base behind.

The cloak is strengthened in the middle above the branchiæ by a thin expanded subspiral shell. The neck is short, and in some contracted, with the front emarginate, exhibiting the commencement of the inferior tentacula. The upper tentacula are tubular and cloven. The gills occur at the edge of the dorsal plate. In front of these are the orifices of the organs of generation, and immediately behind the gills the anus is situated.

The mouth is furnished with a short retractile proboscis. The tongue occupies both sides of the mouth, and is covered with spines. The gullet is enlarged into a kind of crop before it enters the stomach. This is folded, and is divided by contractions into three parts. The first has muscular walls of moderate thickness, with a single longitudinal band. In the second the walls are membranaceous, with longitudinal internal ridges. The third stomach has thin and simple walls. The gut is short. The salivary glands are situated at the folds of the stomach, and empty their contents into the mouth by two canals. The liver is placed on the stomach, and empties itself into the lower part of the crop.

The heart is nearly in the middle of the back. Its auricle is on the right side, at the base of the branchiæ, and the ventricle sends out at the opposite side three arteries.

M. Cuvier has figured and described the P. peronii with its anatomical details. Two species likewise appear to be known as natives of the British seas.

1. *Pleurobranchus plumula*.—Foot pointed behind. Gills in the form of a compound plumose appendage. The cloak contains the shell known to British writers as the Bulla plumula of Montagu, and figured and described in *Testacea Britannica*, p. 214. Vignette 2. fig. 5.

2. *Pleurobranchus membranaceus*.—Foot rounded, with an irregularly indented margin. Cloak covered with conical papillæ. Gills a plumose appendage.

This species was found by Montagu at Kingsbridge, Devonshire, in 1809, and is described and figured by him in the *Linn. Trans.* vol. xi. p. 184. tab. xii. fig. 3, 4.

We have been induced to refer the two species to this genus, as agreeing generally with the characters assigned to it by Cuvier. There is, however, one particular in which they greatly differ. Cuvier states, that the gills in his Pleurobranchi—" sont attachées le long du côté gauche (droit!) dans le sillon entre le manteau et le pied, et representent une serie de pyramides devisées en feuillets triangulaires." *Regne Animal*, iii. p. 396. His representation of the P. peronii, in his Memoires, accords with the preceding description. But in the two British species, the gills appear like a feather, free at one extremity. They may be permitted to remain, therefore, in the genus Lamellaria, which Montagu instituted for their reception, unless we suppose that Cuvier, from inspecting only shrivelled specimens preserved in spirits, overlooked the true structure of the gills, a conjecture we consider as highly probable.

II. APLYSIA. Tentacula four, the eyes placed in front of the two superior ones. Mouth longitudinal.

The body of the Aplysia is ovate, acuminated behind, and produced before to form a neck. The foot is narrower than the body. In the middle of the back is a corneous plate enclosed in a bag in the skin, and on each side, and behind, there is a fold by which this part may be concealed. The head is slightly emarginated, with a feeler on each side. The superior feelers are situated on the neck. In front of each of these is a small black point or eye.

The branchiæ are situated underneath the dorsal plate, on the right side, and exhibit a complicated plumose ridge, capable of expansion beyond the edge of the plate. The anus is situated immediately behind the branchiæ, and before them is the orifice of generation, from which proceeds a groove along the neck to the inferior base of the fore-feeler, on the right side, where there is an opening for the penis.

Within the longitudinal lips are two smooth corneous plates, the substitutes for jaws; the tongue is rough, as in many of the other gasteropoda. The gullet is short, and suddenly expands into a large subspiral crop, with membranaceous walls. To this, a gizzard with muscular walls succeeds, the interior of which is armed with numerous pyramidal teeth, with irregular summits, of a cartilaginous nature. The connection between these teeth and the integuments is so slender, that they are displaced by the application of the smallest force. They however project so far into the cavity, as to offer resistance to the progress of the food. There is yet another stomach, armed on the one side with deflected, pointed cartilaginous teeth. At the pyloric extremity are two membranaceous ridges, between which are biliary orifices, and the opening into a long narrow cæcum, with simple walls, which is contained within the lever. The intestine is simple, and after two turns ends in a rectum.

The salivary glands are very long, and, as usual, empty their contents into the pharynx. The liver is divided into three portions by the folds of the intestine, each of which consists of several lobes. The biliary vessels are very large, and open at the mouth of the cæcum into the last stomach. The food of the Aplysia consists of sea-weeds and minute shells.

The circulating organs are remarkable. On each side the body, in the region of the dorsal plate, there is a large vessel, which receives blood from different parts of the body, and which likewise, by various openings, has a free communication with the cavity of the abdomen. In this respect there is a resemblance to the spongy glandular bodies of the venæ cavæ of the cephalopoda. These two vessels, or *venæ cavæ*, unite posteriorly, and transmit their contents to the gills. The aërated blood is now conveyed to an auricle of large dimensions, and uncommonly thin walls, situated beneath and towards the front of the dorsal plate, and emptying its contents through a valve, into the right side of the ventricle. The aorta, which issues from the left and anterior side, divides into two branches, the smallest of which proceeds to the liver on the left. The larger branch is again divided, the smaller branch proceeding to the stomach. The largest trunk that remains, before it leaves the pericardium, has two singular bodies attached to it, consisting of comparatively large vessels, opening from this aortic branch. The use of these glands is unknown.

The organs of generation likewise exhibit some remarkable peculiarities. The ovarium is situated in the posterior part of the abdomen. The oviduct is tortuous in its course, passes along the surface of the testicle, and after uniting with a clavate appendage, opens into a common canal. The testicle is firm, apparently homogeneous in its texture, of a yellow colour, with spiral ridges on its surface. The vas deferens arises from a complex glandular body, and unites with the common canal. This common duct, before it reaches the external orifice, receives the contents of the pedunculated vesicle, and has attached to it a botryoidal glandular organ, whose use is unknown, but which some suppose to be employed to secrete an acrid liquor regarded as venomous.

It is obvious from this structure, that the seminal fluid and eggs must come in contact in the common canal, and at the single orifice, provided they are both ejected at the same time. From the orifice to the right fore-feeler there is a sulcus, leading to the pore containing the retractile penis. This organ, like those of the other mollusca, is solid. It terminates in a small filament. The external groove is the only connection between it and the other sexual organs.

There is a peculiar secretion of a purple fluid, which here deserves to be recorded. It issues from a spongy texture, underneath the free side of the dorsal plate. Connected with this cellular reservoir is a grandular body of a considerable size, which is supposed to secrete the coloured fluid. This gland is supplied by a large branch of the glandular aorta, and gives out two very large veins to the left vena cava.

The purple fluid itself has never been carefully investigated. It is not altered by the air after drying, nor is its colour destroyed by acids or alkalies, although the tint is a little changed, and rendered less pure. Both these re-agents precipitate from the fluid white flakes.

This liquor is poured out by the animal when in danger, or constrained, and colours the water for several yards around. It ejects it readily when put in fresh water; and when entangled in a net, several yards of it in the neighourhood are sometimes stained, greatly to the amazement of the unsuspecting fishermen.

The Aplysia has been long known in the records of superstition under the name of the *Sea Hare*. Its flesh, and the inky fluid it pours out, have been regarded as deleterious to the human frame. Even to touch it was supposed to occasion the loss of the hair; while the sight of it would not fail to subdue the obstinacy of concealed pregnancy. The progress of science has exposed the errors, or perhaps tricks of the earlier observers, and proves the innocence of an animal formerly invested with every repulsive and noxious attribute.

The species of this genus are still involved in great obscurity. Those which inhabit the British isles appear to be the following.

1. *Aplysia depilans.* Dorsal plates covered in the middle. Body of a purplish-brown colour, with black dots. Length from five to six inches.

This is the most common species, and is found from the south of England to the shores of Zetland. It has a faint disagreeable smell.

2. *Aplysia punctata.* Body brown, with numerous white spots. Dorsal plate exposed in the middle. About the same size as the preceding.

This species was first figured and described by Cuvier, who regards it as distinct. The characters by which they are separated, however, are far from being trustworthy.

The colour in the depilans is subject to considerable variation, and in some cases the black spots disappear. The absence of the cuticle from the middle of the dorsal plate in the punctata, is probably the effect of accident or age.

Both kinds were observed by the late George Montagu, Esq. on the Devonshire coast, and from a letter of his now before us, dated 17th February 1811, he appears to have convinced himself that they did not constitute distinct species. The question can only be decided by the discovery of the intermediate varieties.

3. *Aplysia viredis.* This species is figured by Montagu, *Linn. Trans.* vii. tab. vii. f. 1. and described in the following terms: "With the fore-part of the body like a common *Limax:* tentacula or feelers two, flat, but usually rolled up, and appear like cylindric tubes; at a little distance behind the tentacula, on each side, is a whitish mark, in which is placed a small black eye: the body is depressed, and spreads on each side into a membranaceous fin, but which gradually decreases from thence to the tail, or posterior end: this membranous part is considerably amorphous, but is usually turned upwards on the back, and sometimes meeting, though most times the margins are reflected; this, as well as the back, is of a beautiful grass-green colour, marked on the superior part of the fins or membrane with a few small azure spots, disposed in rows; the under part

with more numerous, but irregular spots of the same: the fore-part of the head is bifid; the lips marked by a black margin: the sustentaculum is scarce definable, as it most commonly holds by a small space close to the anterior end, and turns the posterior end more or less to one side: it sometimes, however, extends itself for the purpose of locomotion, in which it scarcely equals a snail."

"Although this animal does not strictly correspond with the characters prefixed by Linnæus to the genus *Laplysia*, yet it approximates so nearly to the *Depilans* in its external form, that we cannot hesitate to place it with that animal, though we could not discern any membranaceous plate or shield under the skin on the back." The characters here assigned to this species are such as to excite the belief that it is not an Aplysia; but they are not sufficiently minute to enable us to establish another genus for its reception. It is to be hoped that some naturalist, who has an opportunity of visiting the south coast of Devon, where this species was found, will re-examine its characters, and communicate a more detailed account of its form and structure.

III. Dolabella. This genus differs from Aplysia, in the dorsal plate being calcareous and hard. The fore-part of the body is narrow—behind, it is larger, and truncated obliquely. The disk thus formed is circular, surrounded with a fringe of fleshy filaments. From the centre of this disk, a longitudinal slit extends forwards a little way beyond the anterior margin, and contains the branchiæ. The position and structure of the other organs are precisely similar to those of the Aplysia.

This genus was instituted by Lamarck, from characters derived exclusively from the dorsal plate or shell. Cuvier afterwards examined a species brought from the Mauritius by Peron, which he considers as the species figured by Rumphius in his Amboinshe Rariteitkamer, tab. x. No. 6. and which he has consecrated to his memory, naming it Dolabella Rumphii.

IV. Notarchus This genus is desitute of the dorsal plate, and contains an oblique groove on the neck, leading to the branchiæ. The internal structure resembles the Aplysia. This genus was instituted by Cuvier, in his *Règne Animal*, vol. ii. p. 395, and the only known species described, iv. tab. ix. f. 1.

V. Bulla. The animals of this genus differ from the preceding, in the absence of tentacula, and in the foot behind being furnished with a membranaceous appendage.

The body is oblong—becoming a little narrower in front. Below, the foot is broad, thin, and waved on the margin, expanded on each side behind, and capable of being turned upwards. At the posterior part of the foot, there is a broad membranaceous appendage, separated from it by a groove, part of which folds upwards, and a part is spread over bodies, like the foot. It assists in closing the mouth of the shell, and in its position and use is analogous to the operculum, in the following order. Above the foot, in front, but separated from it by a groove, is a flat fleshy expansion, which Cuvier terms the tentacular disk, considering it as formed by the union of the inferior and superior tentacula. In the centre of the disk, in the Bulla hydatis, (*Linn. Trans.* vol. ix. tab. 6. f. 1.) Montagu observed two eyes. Between this portion of the back and the posterior extremity, is the dorsal plate or shell, forming the genus Bulla of conchologists. This shell is covered by the integuments in some species, while in others it is exposed. But in all, the part containing it is partially concealed by the animal, by means of the reflected margins of the foot, and its appendage. Along the right side of the body there is a groove formed by the foot, and its appendage on one side, and the dorsal plate and tentacular disk on the other. The branchiæ are situated in a cavity under the shell or dorsal plate, and resemble those of the Aplysia. Behind the gills, in the lateral groove, is the anus, and in front of these, the orifice of the united organs of generation. The penis is removed as in the Aplysia, and connected by a similar slit.

The mouth is, as usual, in front, above the foot and beneath the tentacular disk, both of which serve as lips. The cheeks are strengthened on each side by a corneous plate. The tongue is well developed in some, as the B. ampulla, while in the B. aperta it is reduced to a small tubercle. The gullet is large, and in the B. ligniaria makes two folds before entering the gizzard. This last organ is fortified by three testaceous plates, convex and rough on the inner surface, and attached to strong muscular walls. These plates exhibit in the different species considerable varieties of form and markings. The intestine, before terminating in the anus, makes several convolutions in the substance of the liver. The salivary glands exhibit considerable differences. In the *B. ampulla*, they are long and narrow, and their inferior extremity fixed to the gizzard. In the *B. aperta* and *lignaria*, they are short, with the extremity free. In the *B. hydatis* they are long, unequal, and the extremity of the one belonging to the left side is forked. The liver forms a part of the contents enclosed in the spire of the shell. It envelopes the intestine, and empties the bile into its pyloric extremity.

The auricle and ventricle appear to occupy the same relative position as in the Aplysia, but the structure of the arteries is unknown. The organs of generation have also so near a resemblance as to forbid a detailed description. Some species are said to eject a coloured fluid like the Aplysia, from the lid of the branchiæ. A gland is observed in the Bulla lignaria, similar to the Aplysia, in which it is probable the fluid is prepared.

The species of this genus have not been sufficiently investigated in a living state. When preserved in spirits, it is impossible to form a correct idea of their true appearance, as exhibited when alive in sea-water, since they usually exist as a shapeless mass. Cuvier has given delineations of such preserved species, but they bear no resemblance to the figures of Montagu, of the same species, taken from living objects.

M. Lamarck is inclined to subdivide this genus into two, distinguishing those in which the shell is concealed by the term *Bullæa*, from such as have the shell in part exposed, which he retains in the genus *Bulla*. The Bulla aperta of British conchologists is an example of the former, and B. lignaria of the latter. The shells of the genus Bullœa are thin and white—those of Bulla stronger, more opake, and covered with an epidermis, which, after the death of the animal, is easily detached.

VI. Doridium. In the animals of this genus, there is no dorsal plate or shell, although there is a cavity with a spiral turn in the cloak. The branchiæ and accompanying organs are nearer the posterior extremity than the species of the preceding genera.

The digestive system is more simple than in the preceding genus. There is here no appearance of the spinous tongue, the gullet is short, and the stomach is membranaceous.

The characters of this genus were first developed by

Cuvier, but the name which we have adopted is that of Mekel. Only one species, D. carnosum, is known as a native of the Mediterranean.

The preceding review of the genera of this order indicates the existence of at least three natural families. The pleurobranchia appears to stand apart, and to have few characters in common with the others, which are all intimately related. But under the head Aplysiæ, the genera Aplysia, Dolabella, and Notarchus, may be included, while the Aceræ will comprehend Bulla, Bullœa, and Doridium.

IV. Order. *Cervicibranchia.*

We have been induced to institute this order, for the reception of the genus Valvata of Muller. The species which it includes are inhabitants of fresh water, and in their general appearance resemble the aquatic pulmoniferous gasteropoda. They are distinguished, however, from all the other gasteropoda, by the position of the branchiæ, and the number of tentacula.

The branchiæ appear in the form of a feather, with a central stem, and a row of compound branches on each side, decreasing in size from the base to the extremity, which is free.

This plume is placed on the neck, near the middle, and a short way behind the anterior tentacula. Near this plume, but on the right side, is a single simple filament, like a tentaculum. The anterior tentacula occupy the usual position, and are setaceous. The eyes are placed at their base behind.

The animal is furnished with a spiral shell, into which it is capable of withdrawing the body. The foot is protected by a spirally-striated operculum, which shuts up the mouth of the shell upon the retreat of the inhabitant.

The species are all of a small size, and their internal structure has never been subjected to a rigorous examination. Two species are natives of Britain.

1. *Valvata cristata.* This is the Helix cristata of Montagu. The shell resembles a planorbis in its depressed form, the whorls revolving nearly on the same plane, so that the last-formed one embraces the others. The aperture is circular and simple. It is found in ditches on aquatic plants in England.

2. *Valvata piscinalis.* This is the Turbo fontinalis of British conchologists, but first described by Muller as Nerita piscinalis. The whorls of the shell form in this species a short spire. It is very common, both in England and Scotland.

V. Order. Pectinibranchia.

This order comprehends nearly all the animals with spiral univalve shells which inhabit the sea, together with a few which reside in fresh water.

The foot is usually fortified above, on its posterior extremity, with a corneous plate, which acts as a lid to the shell, when the animal is withdrawn into the cavity. The anterior extremity is in some of the species double. The anterior margin of the cloak forms a thick band, or arch, rising from the foot, behind which is the portion of the body that is always contained in the shell, and which is covered with a very thin skin. Between the margin of the cloak and foot is situated the head, supported on a short neck. The tentacula are two in number, bearing eyes at their base, or on short lateral processes, which have some claims to be considered as tentacula. The hood is frequently emarginated, and sometimes fringed. The mouth is more or less in the form of a proboscis, in some cases armed within with spinous lips, or furnished with a long narrow spiral tongue, armed with spines, as in the common periwinkle. The nature of this kind of tongue, whose spiral extremity is free and lodged in the abdomen, is not well understood.

The entry to the gills is by a large aperture between the margin of the cloak and neck, at the middle, or towards the right side. These are contained in a cavity on the back of the animal, and consist of leaves arranged in one or more rows, which adhere to the walls of the cavity. At the entrance of this cavity is the anus and oviduct.

The male and female organs are considered not only as distinct, but as occurring on different individuals. The evidence in support of this opinion is in many cases complete. The penis is in some external, and incapable of being withdrawn, while in others it is retractile, and situated in a cavity in the right tentaculum.

The body of the animal is attached to the shell by means of two muscles, which adhere to the pillar near the same place, and shift their position, by an arrangement not well understood, in proportion as the individual increases in size. These muscles terminate in the foot and mouth.

The animals of this order have not been examined sufficiently in detail to admit of their distribution into natural groups, distinguished by characters founded on important differences of organization. The form of the shell has been resorted to, with the view of assisting arrangement. The characters thus furnished would be useful and valuable, were they the index of any peculiar internal structure. But, unfortunately, animals widely different in structure, inhabit shells of the same form, and *vice versa*, so that, however useful the mere conchologist may find the form of the shell to be in his arrangements, it can only be regarded by the zoologist as occupying a subordinate place. Without therefore entering into any details regarding the structure of the few species which may have been examined anatomically, we shall merely point out the tribes and families which have been contemplated, and whose characters in a great measure depend on the shape of the shell.

The first Tribe contains animals with spiral shells, having an entire aperture. The anterior margin of the cloak is likewise entire. It includes the greater part of those shells included by Linnæus in his genera Turbo trochus and Nerita.

The first Family of this tribe, represented by the genus Turbo, has the aperture of the shell nearly round. All the species are furnished with an operculum. Some are known to be ovoviviparous, and it is probable that all the species are so. Some have the sexes distinct, in different individuals, as the Palludinæ, while in others the female organs only have been detected. Some of the genera are marine, such as Turbo, Delphinula, Vermicularia, Turritella, Scalaria, Odostomia, and Monodonta. The animals exhibit remarkable differences in the form of the hood, the length of the peduncles supporting the eyes, and the filaments on the sides of the body.

There is only one genus, the species of which reside in fresh water, termed Paludina. It contains the *Helix vivapara* and *tentaculata* of British conchologists. Cuvier seems disposed to unite with this genus, the common marine shell Turbo littoreus or Periwinkle. The form of the foot and hood, however, are different, but more especially the tongue, which, in the Paludina, is a fixed tubercle, while in the periwinkle it is strap-shaped, free at one extremity, equal in length to the body, and covered with spines.

The second Family is represented by the Linnean genus Trochus The aperture of the shell is somewhat quadrangular. The foot of the animal is furnished with an operculum, (unless in the genus Pyramidella, in which it is supposed to be wanting,) and the body on each side is ornamented with filaments, usually three in number, resembling tentacula. All the species are marine, and are included in the genera Trochus, Solarium, and Pyramidella.

The third Family, termed Conchylium by Cuvier, is formed of shells having the aperture crescent-shaped, as in the genus Helix, in which they were formerly included. Two of the genera, Ampullaria and Melania, are fluviatile, residing in the countries near the equator. The remaining genera, Phasianella and Janthina, are marine. The Janthina vulgaris is destitute of an operculum, but in its stead it is generally furnished with a cellular spongy body adhering to the foot, which, in consequence of changes produced in its density by unknown means, enables the animal to rise to the surface of the water and float. When restrained, it throws out a purple fluid, like the Aplysia, lodged in the margin of the cloak, covering the gills.

This species has been added to the British Fauna by the late Miss Hutchins, who obtained many individuals from a herd of them which came into Bantry Bay. They have since been found on many other parts of the Irish coast.

We are disposed to place here, as a new genus, the *Bulla velutina* of Muller, figured and described in the Zoologia Danica, tab. ci. fig. 1, 2, 3, 4. It is the Helix lævigata of British writers. The foot is destitute of lid or appendage, and is broad before and pointed behind. The tentacula are two in number, short and filiform, with eyes at their external base. The head is broad and short. In addition to these characters given by Muller, we have been enabled to add the following, from a specimen, somewhat altered, which was found in the stomach of a cod-fish. The animal adheres to the shell by two linear muscles, one on each side the cloak. The branchial cavity is towards the left side. The tongue is spinous, narrow, with its free extremity spiral. Eyes rather behind the tentacula. Penis exserted on the right side of the neck, immediately behind the eye. Cloak large in proportion to the size of the foot. We have termed the genus *Velutina*, bestowing on the species the trivial name *vulgaris*.

The fourth Family includes the Neritæ of Linnæus, distinguished by the oblique straight pillar lip, and semicircular aperture, closed by an operculum. Two of the genera of this family, Natica and Nerita, are marine, while the Neritina, represented by the Nerita fluviatilis of Linnæus, lives in fresh-water streams.

The Second Tribe includes the spiral canaliculated univalves of conchologists. The aperture of the shell at its anterior margin is formed into a groove or canal. This structure is occasioned by the anterior margin of the cloak being produced over the aperture of the gills, for the purpose of acting like a syphon or tube, to convey the water to and from the branchial cavity. The species are considered as oviparous, with distinct sexes in separate individuals.

The first *Family* includes the genus *Conus* of Linnæus. The animals are furnished with a long proboscis, and tentacula, the latter bearing the eyes near the summit on the outside. The lid is placed obliquely on the foot, and is too small to fill the mouth of the shell. The species, which nearly amount to two hundred in numder, are all inhabitants of the seas of warm countries. They are now arranged under the genera Conus and Terebellum.

The second *Family*, represented by the genus Cyprea, contains likewise many species. The cloak of the animal is sufficiently large to admit of its extension over the surface of the shell. The animal casts its shell as it increases in size, and forms a new one suited to its dimensions, as we have formerly stated. When the shells are obtained before they have received their external coat, they have been regarded as new species. The foot is destitute of a lid.

The third *Family* consists of the genus *Ovula* of Bruguière. The animals of the different species are unknown. The shells have been distributed into the following genera by Montfort—Ovula, Calpurna, and Volva. The last includes a British shell, the Bulla patula of Pennant.

The fourth *Family* includes the Volutæ of Linnæus. The genera, which are the following, appear to be destitute of a lid. Voluta Oliva, Cymbium, Marginella, Cancellaria, Colombella, Mitra Ancilla, Volvaria, and Tornatella.

The fifth *Family* is represented by the genus Buccinum of Linnæus. The canal is short, scarcely produced beyond the anterior margin of the lip, and bent towards the left. All the animals which have been examined are furnished with a retractile proboscis. The eyes are situated at the external base of the tentacula; and the foot is furnished with a lid. The following genera have been established in this family: Buccinum, Eburna, Dolium, Harpa, Nassa, Purpura, Cassis, Morio, Terebra, Cerithium, and Potamida. In the two last the head is furnished with a hood, of which the former genera are destitute.

The sixth *Family* consists of the genus Murex of Linnæus. The canal of the aperture is straight, and more or less produced. The inhabitants exhibit nearly the same form as those of the preceding family. The following genera appear to be formed on permanent characters: Murex, Typhis, Ranella, Fusus, Pleurotoma, Pyrula, Fasciolaria, and Turbinella.

The seventh *Family* includes the Strombi of Linnæus. These possess a canal which is short, and either straight or bent towards the right. The outer margin of the aperture is expanded with age, and exhibits a second canal, generally near the former, for the passage of the head. The following genera belong to this family: Strombus, Pterocera, Rostellaria.

The Third Tribe is represented by the Helix haliotoidea of Linnæus, now constituting the genus *Sigaratus*.

The foot of the animals belonging to this family, or rather of the species which constitutes the type, is oval, with a duplicature in front. The cloak is broad, with an indentation on the left side, in front, leading to the branchial cavity. A ring of transverse muscles unites the cloak with the foot. On the back is placed the shell, which does not appear on the outside, as it is covered by a thick cuticle. It is lodged in a sack, and united by a muscle, which adheres to the pillar. The hood is produced, at each side, into a flattened tentaculum, with an eye at the external base. The anus is situated at the branchial indentation on the left side. The penis is situated on the right side of the neck. It is external, with a crooked blunt lateral process near its extremity.

The mouth is in the form of a short proboscis. The tongue is armed with spines, and is long and spirally folded. The salivary glands are large. The stomach is membranaceous, giving off the intestine near the cardia. The intestine makes two folds. The liver, with the testicle in the male, and the ovarium in the female, occupy the posterior part of the body, under the spire of the shell. Two species are natives of Britain.

1. *Sigaretus haliotoidea.*—The tentacula in this species are short and flat, and the foot rounded behind. It is figured imperfectly by Montagu in *Testacea Britannica*, vignette 2. fig. 6. It occurs frequently on various parts of the coast.

2. *Sigaretus tentaculatus.*—The tentacula are produced and filiform. The foot pointed behind. This species was discovered by Montagu at Kingsbridge, Devonshire, in 1809, and described and figured by him in *Linn. Trans.* vol. xi. p. 186. *tab.* xii. fig. 5 and 6.

The animals of this order were formerly valuable in an economical point of view. Many of them yield a rich dye, which was much sought after by the ancients. This was chiefly extracted from the animal of the Murex Brandaris, and was termed Purpura. But it is likewise furnished by the animals of Purpura lapillus, Scalaria clathrus, and Planorbis corneus. Since the introduction into Europe of the Cochineal insect, the use of this dye has been superseded, so that we are now in a great measure ignorant of the process which the ancients employed to extract it.

The Pectinibranchiæ, although no longer sought after as furnishing colour for enriching dress, are still in estimation as articles of food. The Periwinkle is frequently gathered by children in this country, as well as the Nerita littoralis, and eaten when boiled. The welk and buckie are likewise sought after. All these animals are extensively employed as baits for catching fish.

VI. Order Scutibranchia.

This order was instituted by Cuvier, for the reception of animals whose general form and respiratory organs are similar to the Pectinibranchiæ, but which differ, in his opinion, in so many other particulars, as to warrant their separation. They chiefly belong to the old genera, Halyotis and Patella.

The sexes are united in the same individual in such a way as not to require union with another; or, rather, the male organs are unknown. The heart is traversed by the rectum, and is furnished with two auricles. The cloak is protected on the back by a conical or subspiral shelly-shield, into which the animal is capable of withdrawing itself. The foot is destitute of a lid. The following genera have been established in this order.

1. Halyotis. The shells of the animal of this genus have frequently been described, but it is to Cuvier that we owe the most accurate details concerning the structure of their inhabitants. The foot is oval and large. The sides of the body all round are ornamented with one or more rows of simple or branched filaments. The shell is placed on the back, with the spiral part behind, and the row of holes on the left side, through which some of the filaments are protruded. The animal is attached to the shell by a single large muscle. The entry to the branchial cavity, which likewise contains the termination of the rectum and oviduct, is on the back. The gills are in two ridges, consisting of complicated branched filaments. At the entrance of the cavity, the cloak is furnished with a slit, the left margin of which rests upon the pillar of the shell. The edges of this slit are furnished with filaments, which pass through the anterior holes of the shell. The use of this singular arrangement is unknown. The branchial cavity likewise contains the viscous organ, in common with the Pectinibranchiæ.

The hood is emarginate, with a long tentaculum on each side, behind which, towards the side, is a cylindrical protuberance, bearing the eye at the top. The mouth is in the form of a short proboscis, with two corneous plates as cheeks, and a long narrow tongue extending backwards, and covered with spines. The pharynx is dilatable, with internal folds. The salivary glands are very small. The gullet is very short. The stomach is divided into two portions. The first is striated longitudinally with a glandular structure, and receives a biliary duct. The second is separated from the former by a valve, is smaller, with transverse striæ, and a double ridge. It likewise receives bile through two apertures. There is another valve at the pylorus; and the intestine, after making some turns, is surrounded by the heart. There is an auricle on each side, receiving the aërated blood from each of the gills.

The species of this genus are by no means numerous. Montfort separated those in which the marginal holes were nearly obliterated, with an internal groove and external ridge in the line of their direction, and formed them into a genus which he terms Padolles. Lamarck likewise separated those whose shells are destitute of the marginal holes, under the generic appellation Stomatia.

2. Capulus. This genus is represented by the Patella hungarica. The foot is complicated on its anterior margin. The shell adheres to the animal by a circular muscle, leaving an opening in front, for the issue of the head and entrance to the branchial cavity. The gills form a single ridge across the roof. The mouth is in the form of an extended proboscis, with a deep groove above. The tentacula, which are two in number, have the eyes at the external base. The anus is on the right side of the branchial cavity.

We possess two species of this genus in our seas, Hungarica and Antiquata, to which M. Cuvier is disposed to add the Bulla velutina of Muller. This last shell, however, we have already noticed as belonging to the Pectinibranchiæ.

3. Fissurella.—The animals of this genus have the foot like the preceding, and the back is protected by a conical shell perforated at the apex. The shell is united to the cloak by a circular muscle, open in front. The cloak forms a duplicature in front for the branchial cavity, which extends to the perforated apex of the shell. The gills consist of two ridges; at the dorsal extremity of which is the anus. It is probable that the excrements are ejected at the perforation in the apex of the shell, and likewise the water which enters the branchial cavity in front. The head is furnished with two tentacula, bearing the eyes at the external base.

The Patella græca and apertura may be quoted as British examples of the genus.

4. Emarginula.—This genus differs from the former

in the apex of the shell not being perforated. Its place, however, is supplied by a slit on the anterior margin, the entrance to the branchiæ and anus. The foot is surrounded with a row of filaments, and the eyes are supported on short foot-stalks, characters in which it approaches the genus Halyotis. The Patella fissura of conchologists is considered as the type of the genus.

5. Crepidula.—The shell of this genus is conical, with the apex obliquely directed to the right side behind. From the hinder part of the cavity there is a thin plate or horizontal projection, which serves as a support to the abdomen. The gills form a transverse ridge on the roof of the cavity. They consist of simple filaments, which extend considerably beyond the margin of the cavity. The eyes are placed on the head, at the base of the tentacula. The Patella fornicata is the type of the genus.

6. Navicella.—The shell in this genus differs from the former in the apex being mesial, and the horizontal plate smaller. The abdominal sack likewise contains a loose, irregular, angular, testaceous body, a character of which there is no other example among the gasteropoda. The species appear to be fluviatile, living in the rivers of warm countries. The Patella neritoidea is the type of the genus.

7. Calyptrea.—The animal of this genus is not known. But the characters of the shell are well marked. It is conical, with a spiral lamina descending from the apex in the interior, marking the commencement of a pillar. The Patella chinensis of British writers may be quoted as an example of the genus.

8. Carinaria.—This genus was instituted by Lamarck, for the reception of the shell termed Argonauta vitrea. The animal has hitherto been imperfectly examined. The foot appears to be compressed, and formed for swimming. The head is covered with a group of tubercles. The mouth is furnished with a proboscis. Near the middle of the body, the shell is attached. The surface of the body above is closely covered with small tubercles. It is probable that the species here alluded to is the same with the Pterotrachea coronata of Foraskæl.

Although these genera have been constituted into a separate order, it is probable that in a natural arrangement they might more conveniently be placed with the Pectinibranchiæ. The position of the heart is indeed singular; but as this organ varies greatly in its form and position in different genera, the characters which it furnishes are, consequently, of doubtful value. The nature of their hermaphroditism has never been satisfactorily investigated.

IV. Class.—CONCHIFERA.

The molluscous animals which are destitute of a head, were separated at an early period, by Cuvier, into a distinct order, to which he gave the name of Acephala. Subsequent observations having pointed out the character of being acephalous, as common to animals which differ widely from one another in the arrangement and disposition of their other organs, it became necessary to introduce into the system a more definite method of arrangement. Accordingly, Lamarck, in his "*Histoire Naturelle des Animaux sans Vertebres*," v. p. 411, instituted the class Conchifera, which includes nearly all the inhabitants of the bivalve testacea, or those whose gills are in the form of leaves, four in number, and disposed in pairs externally, on each side the abdomen, and within the cloak. As the bivalve shells were long known to naturalists under the denomination Conchæ, the propriety of the term to designate the class, employed by Lamarck, is sufficiently obvious.

The common integuments of the Conchifera, consist of the cloak and shell. The cloak forms two leaves, one on each side the body of the animal, united behind. This cloak is, in some families, open in front, while in others, it is united; perforated, however, by holes, or tubular elongations, termed syphons, for admitting water and food. Corresponding with the two sides of the cloak, are the two valves of the shell. These valves are likewise united behind with an elastic ligament, which aids the animal in opening and shutting them. The shells are attached to the animal by the anterior margin of the cloak, which adheres to the margin of the shell, and by the adductor muscle. This muscle, which passes across the body from one valve to another, brings the valves, by its contractions, into contact, at their free edges, at the same time that the ligament is compressed or stretched, according as it is internal or external. When the muscle is relaxed, the ligament exerts its power, and opens the valves; and along with the valves, the cloak to which they are attached. The adductor muscle is in some families divided, and the two portions separated from each other.

Locomotion is performed in some to a limited extent, by suddenly opening and shutting the valves. In general, however, those species which shift their place are furnished with a muscular projection from the body, capable of changing its shape, and attaching itself to foreign bodies, termed a foot. The base of the foot is usually attached by two or more tendinous filaments to the shell. The *byssus* issues from a muscular body, likewise connected by filaments with the shell, and is fixed to other bodies. The foot is supposed to be the organ which spins this thread; but its mode of formation is involved in obscurity. While some are permanently fixed, and others are capable of moving from one place to another, there are a few which prefer a residence in different substances in which they have excavated a habitation. These last are termed *Borers*. It was supposed by many that the animal secreted a liquor, with which it dissolved the bodies into which it penetrated; but the sagacious Reaumur soon ascertained that the boring was performed by means of a rotatory movement of the larger valves. M. Fleurieu Bellevue states, that the calcareous stone, in which the Rupellaria lithophaga is found, is often discoloured in the immediate neighbourhood of its recess. This may arise from the secretions of the animal, or even from the stagnant sea water in the hole, and not from the action of the phosphoric acid, or any other solvent supposed to be employed by the animal. These solvents would act equally on the shell as on the calcareous rock. But the borers are not confined to calcareous rocks: they also lodge in slate-clay, and other argillaceous strata. This is very often the case with the Pholades. But this character can never be extensively employed in the distribution of genera, as the same species which, at one time, may be found imbedded in stone, will be observed, at another, seated among the roots of sea-weed, or buried among gravel.

The nervous system is here more simple than in the animals of the preceding classes. There are no ganglia scattered through the body; all the nervous filaments taking their rise either from the medullary mass above the entrance to the stomach, or from the one beneath. Although the body does not appear liberally supplied with nerves, yet the sense of touch is exquisite, particularly in those filaments or tentacula with which the margin of the cloak, or its apertures, are provided. No organs of sight or hearing have been observed.

The food of the Conchifera appears to be obtained exclusively from the substances floating or mixed with the water. These are brought within the sphere of the mouth by the movements of the cloak. The mouth itself is destitute of proboscis, jaws, tongue, or even lips. Around its margin are four tentacula, which, in structure, bear a considerable resemblance to the branchia. The mouth opens immediately into the stomach, without the intervention of any thing which can be called a gullet. This organ is usually full of cells; the bottom of each pierced with a biliary duct. The liver surrounds the stomach, and empties its bile by numerous openings. A singular *crystalline process*, cylindrical, cartilaginous, and transparent, projects into the cavity of the stomach, whose use has not been determined. There is sometimes an enlargement, in the form of a second stomach. The intestine, in some species, makes several convolutions; in others, particularly those which are fixed, it is remarkably short. The anus is placed in the extremity of the body, opposite to the mouth, and either opens into the cavity of the cloak, or into one of its syphons.

The only organ of reproduction hitherto observed in this class, is the ovarium. This occupies the sides of the body, and penetrates the membranes of the cloak. The eggs pass into the gills, where they are hatched, and, bursting the integuments, make their escape. In the ovarium has been observed, at certain seasons, a milky fluid, regarded as *sperm*. There appears to be no reason to infer the existence of any thing like sexual union. Lamarck is supposed to consider fecundation as effected by means of an impregnating fluid mixed with the water, which must therefore have been ejected from male organs. This supposition, however, is neither supported by facts nor analogy.

The most important of the peculiar secretions of the animals of this class, is the Pearl. This substance, equally prized by the savage and the citizen, is composed, like shells, of carbonate of lime, united with a small portion of animal matter. Pearls appear to be exclusively the production of the bivalve testacea. Among these, all the shells having a mother-of-pearl inside, produce them occasionally. But there are a few species which yield them in the greatest plenty, and of the finest colour. The most remarkable of these is the *Avicula margaritifera*. This shell, which was placed by Linnæus among the mussels, is very widely distributed in the Indian Seas; and it is from it and another species of the same genus, termed *Avicula hirundo*, found in the European seas, that the pearls of commerce are procured. The *Pinna*, so famous for furnishing a byssus or kind of thread, with which garments can be manufactured, likewise produces pearls of considerable size. They have seldom the silvery whiteness of the pearls from the Avicula, being usually tinged with brown. But the shell which in Britain produces the finest pearls, is the *Unio margaritifera*, which was placed by Linnæus in the genus *Mya*. It is found in all our alpine rivers. The Conway and the Irt in England, the rivers of Tyrone and Donegal in Ireland, and the Tay and the Ythan in Scotland, have long been famous for the production of pearls. These concretions are found between the membranes of the cloak of the animal, as in the Avicula, or adhering to the inside of the shell, as in the Unio. In the former case, they seem to be a morbid secretion of testaceous matter; in the latter, the matter appears to be accumulated against the internal opening of some hole, with which the shell has been pierced by some of its foes. Linnæus, from the consideration of this circumstance, endeavoured, by piercing the shell, to excite the animal to secrete pearl; but his attempts, though they procured him a place among the Swedish nobility, and a pecuniary reward, were finally abandoned; the process being found too tedious and uncertain to be of any public utility. The largest pearl of which we have any notice, is one which came from Panama, and was presented to Philip II. of Spain, in 1579. It was of the size of a pigeon's egg. Sir Robert Sibbald mentions his having seen pearls from the rivers of Scotland as large as a bean.

All the animals of this class inhabit the waters. A few species live in pools, lakes, and rivers, preferring fresh water; but the sea contains the greatest numbers.

The following arrangement of the genera is the one adopted by M. Cuvier in his "*Règne Animal.*" As it stands at present, it brings together into groups nearly allied genera, without, however, distributing them, with much accuracy, into natural families.

Section I.

In the Conchifera which are brought together in this section, the cloak is open, and the water comes directly in contact with the gills and mouth. The foot, when it exists, is very small; and, instead of aiding locomotion, appears to be principally employed in forming and fixing the threads of the byssus. Many of the species are cemented to the rocks from infancy to old age, others are capable only of shifting to a short distance, by violent exertions, consisting in suddenly opening and shutting their valves.

I. Tribe.—The animals of this tribe is distinguished by possessing only one adductor muscle for closing the valves of the shells, which are inequivalve. The distribution of the genera into natural families, is at present impracticable, as the animals of few of the species have been investigated with any degree of care.

In the genus Ostrea, represented by the common oyster, the abdomen is prominent, the adductor muscle central, and the branchiæ united at their summits with the edge of the cloak. The animals of the genera Acardo and Gryphœa, are unknown.

In the animals of the genus Pecten, represented by the common scallop, there is a small foot, supported on a short stalk arising from the abdomen. The margin of the cloak is surrounded with two rows of tentacula, some of which, in the external row, have greenish tuberculated summits. The mouth is surrounded with numerous branched tentacula, in place of the four ordinary labial appendages. The genera Lima and Pedum are nearly related to the genus Pecten, with which they constitute a particular family.

The genus Anomia, as now restricted, is distinguished by the singular character of the adductor muscle, a portion of which is attached to the corneous or testaceous plate, which passes through the cardinal perforation, and adheres to rocks. There is a small foot, which is capable of being likewise protruded through the cardinal perforation.

In the genus Spondylus, the margin of the cloak is fringed with a double row of tentacula, with tuberculated summits, and the foot is seated on a short stalk, with a large radiated disk.

Besides the genera already noticed, the Placuna, Plicatula, Malleus, Vulsella, and Perna, likewise belong to this tribe. Many of the species are eagerly sought after as food, as the oyster and scallop, and give employment to several thousands of the inhabitants of this country, in fishing, and conveying them to the market.

In the revolutions which molluscous animals have undergone, the genera of this tribe appear to have suffered greatly. Multitudes of extinct species, and even genera, are to be found in the solid strata, differing in shape and size from those which are now found in our seas. We are disposed to refer to this extinction of genera, as accounting for the circumstance, that in this tribe almost every genus stands apart, and appears to be but remotely connected with those with which it is now associated, the connecting links having been destroyed.

II. Tribe.—The valves in this tribe are moved by means of two adductor muscles, one of which is placed near the head, and the other at the anus of the animal.

The pearls produced by the animals of the genus Avicula have been long known, and highly prized; but their anatomy and physiology are still involved in obscurity. The *A.* hirundo has been determined by Mr. Sowerby to be a native of the British seas, he having obtained specimens both from Marazion and Bantry Bay. In the genus Crenatula of Lamarck, which is intimately connected with the preceding, there is no mark indicating the animal to have a byssus, which the Avicula is known to possess.

The genus Pinna has been long known and highly prized by collectors. The mouth of the animal is situated near the narrow end of the shell. Near the anus there is a conical appendage, susceptible of enlargement and contraction, whose use is unknown. The thread or byssus with which the animal adheres to the sand in which it resides, is collected on the Neapolitan coast; and when mixed with silk, is woven into various articles of dress, as gloves and stockings.

The genera Arca, Pectunculus, and Nucula, form a family formerly included in the genus Arca of Linnæus. The animals of the genus Arca have a pedal ligament, with which they adhere to different bodies. The animal of the Pectunculus, on the other hand, is furnished with a large compressed foot, with which it is able to crawl. The inhabitant of Nucula is unknown.

Section II.

The animals of this section have two adductor muscles. The cloak is open in front, with a separate aperture behind, for the passage of the excrements. The shells are equivalve. The species were formerly included in the genus Mytilus.

In the restricted genus *Mytilus*, represented by the common mussel, the beak is terminal. The margin of the cloak, at the rounded angle of the front of the shell, is fringed with branched tentacula. In the genus *Modiolus*, represented by the Mytilus modiolus of Linnæus, the beak is removed a little way from the anterior extremity. In the *Lithodomus* of Cuvier, which includes *Mytilus lithophagus*, both extremities of the shell are equally rounded, whereas in the Mytilus and Modiolus, the anterior is the most pointed. In these three genera there is a foot and byssus.

The genera *Anodonta* and *Unio* are inhabitants of fresh water, resembling each other in the form of the animal, but differing in the structure of the hinge of the shell, the former being destitute of the teeth possessed by the latter. The foot is large and compressed. The posterior end of the cloak is fringed with small tentacula. The Anodonta is represented by *Mytilus anatinus*, and Unio by *Mya margaritifera* of Linnæus. M. Cuvier considers the genera Cardita, Venericardia, and Crassatella, as nearly allied to the genera of this section.

Section III.

This section includes at present only two genera, Tridactina and Hippopus. The cloak is furnished with three openings, all of them near the anterior extremity. The first of these is the largest, and serves for the passage of the byssus. The second admits the water to the branchiæ, and the third is opposite the anus. The valves are closed by one adductor muscle.

Section IV.

The animals of this section resemble those of the last in the three apertures to the cloak. The first is large, and the two last are sometimes produced into separate or united tribes. The foot issues from the anterior opening, while the two posterior apertures serve for respiration and the passage of the excrement. There are two adductor muscles for closing the shell, one near the mouth, and the other at the anus.

In the genus *Chama*, the two posterior apertures are in the form of short tubes, the anterior one is small, and indicates the corresponding size of the foot. The foot of the animals of the *Isocardia* is much larger, and the anterior aperture is large in proportion.

In the common cockle (Cardium,) prized by many as an agreeable article of food, the foot occupies a large share of the cavity of the shell. It is bent in the middle, with the point directed forwards. Cockles are considered in season during March, April, and May. They are sold in this country by measure, and eaten either raw, or boiled and pickled.

In the genera Cyclas, Tellena, Donax, and Venus, the foot is long and tongue-shaped, and the posterior tubes, in general, considerably produced, and more or less united at the base. In the genus Loripes, the foot is small and cylindrical, and the tubes short and united. In the Mactra the tubes are likewise short, but the foot is compressed.

Section V.

In the animals of this section the cloak is united in front, with an opening at the anterior extremity for the passage of the foot, and a production at the other extremity in the form of two united tubes. The cuticle of the cloak is continuous with that which invests the shell. Hence, when the animal is removed, the cuticle frequently remains on the margin of the valves in loose membranes.

The animals of the different genera are constructed nearly on the same plan, so that it is impossible, without the aid of the shell, to give them any definite arrangement. The following genera are considered as belonging to this section: Mya, Lutraria Anatina, Glycymeris, Panopea, Pandora, Gastrochæna, Byssomia, Hiatella, Solen, Sanguinolaria Pholas, Teredo and Fistularia. They all appear to prefer concealment, lodging in the sand, in stones or wood. Many of them are used as food, as the Razor-fish (Solen,) and Gapers (Mya.)

Class V.—TUNICATA.

This class was first instituted by Lamarck in the year 1816, and has now been generally adopted by naturalists. It includes the "Acephales sans coquilles" of the system of M. Cuvier, and embraces several of the zoophytes as well as mollusca of the system of Linnæus.

The animals of this class are all naked, the external covering being soft and coriaceous. There are two apertures, one for the use of the gills in respiration, and the other for the digestive organs. These apertures are frequently surrounded with productions in the form of tentacula. The inner cloak is in many genera loose, in others adhering, but in all it is united with the external one at the two apertures. These sacs are furnished with muscular bands and filaments; and traces of a nervous system have been perceived. The alimentary canal is very simple, and scarcely can be distinguished into gullet, stomach, and intestine. The liver adheres to the stomach, and in many is divided into distinct lobes. The gills cover the walls of the cavity of the inner tunic. They are in the form of ridges more or less complicated. The circulating system appears to be reduced to a single systemic ventricle. The organs of reproduction consist of an ovarium, either simple or complicated, with some additional glands, whose uses are not ascertained.

All the animals of this class live in the sea, and are very widely distributed. Some of them are fixed to rocks and sea-weeds, others move about in the water. Many genera possess species whose individuals are detached and independent, while with others there is an inseparable union. These united individuals constitute a symmetrical mass, in some cases capable of moving about in the surrounding element.

The investigation of the structure of this class of animals has been conducted with great care and success by M. Savigny, in his "*Recherches anatomiques sur les Ascidies composées et sur les Ascidies simples*," inserted in his "*Mémoires sur les Animaux sans Vertèbres*." Paris, 1816. MM. Desmaret and Lesueur have likewise contributed materially to unfold their structure. The labours of these authors, together with Cuvier's papers on the genera Salpa and Ascidia, embrace nearly all the information which has been obtained regarding the structure and physiology of the animals which have been brought together in this class. It is our intention to give a brief exposition of the systematical characters of genera, according to the method followed by M. Savigny.

Subdivision I. Tethydes.

In this subdivision the inner tunic is detached from the external covering, except at the two orifices. The branchiæ are large, unequal, and cover the walls of the great cavity. The opening to this cavity is surrounded on the inside with a membranaceous, denticulated ring, or with a circle of filaments.

Order I.

The animals of this Order are all fixed to other bodies, without the power of displacing themselves. The branchial and anal openings are neither opposite, nor do they communicate directly with each other. The branchial cavity is open at its upper extremity only, and the aperture is fringed with tentacula; the gills of both sides are continuous. The genera are distributed into two sections.

Section I.

This contains the animals formerly included in the genus Ascidia of Linnæus. They are distinguished by the separate or independent existence of the different individuals. In some species many individuals adhere to the rock in clusters, and appear to constitute one animal; but these can be easily separated, as they possess no common covering or organical connection. The genera of this section are four in number, and are distributed into two families. In the first family the orifices are furnished with four rays, and the genera are *Boltenia* and *Cynthia*, the former represented by the Ascidia pedunculata, having the body supported on a stem, while in the latter the body is sessile, as in C. conchilega, a native of the British seas.

In the second family, the anal and branchial openings are either destitute of rays, or they exceed four in number. The genera are two. In the *Phallusia* the body is sessile. The branchial orifice usually possesses eight rays, and the anal one six. The P. *mentula* is very common on rocks and old oysters in the British seas. The P. *intestinalis* and *prunum* are likewise natives. In the genus *Clavelina* the body is pedunculated, and the apertures are destitute of rays. The C. *lepadiformis* has been added to the British Fauna by the industry of Dr. Leach. The genus Mammaria of Muller will probably constitute a third family in this section, when its structure has been determined. The body is smooth, having the base fixed to sea-weeds, and the summit perforated by a single aperture. One species, the M. mammilla, inhabits the British seas, having been observed at Leith by Professor Jameson, and at Belfast by Mr. Templeton. The genus Bipapillaria of Lamarck is involved in equal obscurity.

Section II.

In this section are included animals which were formerly placed among the zoophytes, and chiefly in the genus *Alcyonium*. They are compound animals, many individuals being united under a common covering. They admit of division into three families.

In the first family the branchial and anal orifices have six rays each. The genera of this family are three in number. The *Diazona* is distinguished by the body being sessile, orbicular, and consisting of a single system or group of individuals. The D. *violacea* of Savigny is the only known species. In the *Distoma* the body is sessile and polymorphous, and the individuals are arranged in systems or groups. The D. variolosus, first observed by Gartner, is a native of our seas, and is the Alcyonium ascidioides of Pallas. In the *Sigillina*, the body is conical and pedunculated, consisting of a single group of individuals. The S. australis of Savigny is the only known species.

In the second family the branchial orifice only has six regular rays. The genus *Synoicum* has the body cylindrical, vertical, and pedunculated with a single system. The S. turgens of Phipps, a native of the Arctic seas, is the only species which has been described. In the month of August 1817, we observed a Synoicum, adhering to a rock in the sea at the Isle of May. It differed from the *turgens*, as described by Savigny, chiefly in the smoothness of the skin. In the *Sydneum* the body is inversely conical, vertical, pedunculated, with a single system. The S. turbinatum, observed by Dr. Leach as a native, is the only known species of the genus. In the genus *Alpidium*, the body is variously shaped, sessile, consisting of many systems, which are destitute of a central cavity. The *A. ficus*, or Alcyonium pulmonaria of Ellis's zoophytes, belongs to this genus. In the *Polyclinum* the body is likewise sessile, but the individuals are in systems with central cavities. The *Didemnum* is sessile, spongy, and incrusts other bodies. The anal opening is obscure.

In the third family, both the branchial and anal orifices are destitute of rays. The body invests fuci and rocks, and consists of several systems. In the genus *Eucœlium*, the systems are destitute of central cavities. In the genus *Botryllus*, on the other hand, there is a central cavity to each system. The last genus contains the following British species: B. *Leachii, Borlassii, Scholosseri*, and *Conglomeratus*.

Order II.

The animals which remain to be considered, as constituting this order, are free, and float about in the water. Many individuals are united, forming a conical bag. The anal and branchial openings are diametrically opposite to each other. The branchial cavity is open at both ends, the anterior aperture is destitute of tentacula, but furnished with a denticulated ring. The branchiæ are disjoined. There is only one genus in this order known, which has been termed *Pyrosoma*. It contains the following species, *verticillata*, *paniculata*, and *atlanticum*.

Subdivision II.—Thallides.

This subdivision embraces animals whose inner tunic adheres to the external one at all points; whose branchial orifice is furnished with a valve; and whose branchiæ consist of two united narrow leaves.

The animals here referred to were first formed into a separate genus by Brown, in his *History of Jamaica*, under the title Thalia, a name now usurped by Flora. Forskael afterwards instituted his genus Salpa, and Sir Joseph Banks the Dagysa, for the reception of similar animals. The name of Forskael has been preferred by naturalists. Few of the species have been examined in a recent state. They appear to be numerous, and to exhibit a considerable variety of character; perhaps sufficient to warrant their distribution into several distinct genera. They appear to inhabit chiefly the seas of warm climates.

Class VI.—BRACHIOPODA.

This class was instituted by M. Cuvier, in consequence of an examination of the animal of the Patella unguis of Linnæus. Its characters are well marked, and abundantly justify the propriety of the change. The animals of this class are acephalous; and, like the conchifera, have the cloak divided into two lobes, protected by a bivalve shell. These lobes are free at the anterior margin. The branchiæ consist of small leaves, arranged along the inside of the edge of the cloak, and intimately united with it. From the body, between the lobes of the cloak, issue two arms, fringed with filaments. These are capable of folding up in a spiral form. The mouth is situated between the arms at the base.

All the animals of this class are inhabitants of the sea, and they are permanently attached to rocks and stones. Three genera are known, which are probably the types of as many orders.

1. *Lingula*. The valves of the shell of the species which constitutes this genus were first figured by Seba, together with the peduncle by which they are supported. Linnæus, having seen only one valve, conjectured that it belonged to the Patella, and named it P. unguis. Chemnitz examined both valves, without the peduncle, and pronounced them connected with the genus Pinna. Bugiere, aware of Seba's figure, contemplated the formation of the new genus for its reception, which Lamarck executed. M. Cuvier afterwards dissected one of the individuals which Seba had possessed, and unfolded characters in its organization, sufficient not only to warrant the construction of a new genus, but a new class.

The peduncle of the Lingula is cartilaginous, having the inferior ends of the two oval valves attached to its extremity, the other end being fixed to foreign bodies. The valves are destitute of teeth, or an elastic ligament, and are opened chiefly by the arms when pushed out, and closed by the adductor muscles, which are capable of acting in an oblique direction, and of giving to the valves a considerable degree of lateral motion. The margin of the cloak, which is double like the shell, is fringed with fine hairs. The arms are fleshy in their substance, conical, elongated, and compressed in their form, and ornamented on the external surface with thickset fringes or tentacula. The mouth is situated between the arms at their base, and is simple. There is no enlargement of the alimentary canal, which can be regarded as a stomach, and the anus is a simple aperture, situated on the side. There are marked indications of salivary glands and a liver. The blood is conveyed to the gills by two vessels, which are divided at the separation of the lobes into two branches, one of these going to the half of one lobe, and another to the opposite half of the other lobe. Two systemic veins occupy a similar position, and return the aërated blood to the two lateral systemic ventricles. The gills themselves are arranged in a pectinated form on the inner surface of each lobe of the cloak. There is nothing known of the nervous or reproductive systems of this animal.

The Lingula unguis is the only species of the genus, and appears to be confined to the Indian seas. Some petrifactions have recently been referred to this genus; but in the absence of all vestige of the peduncle, we do not consider the mere form of the shell as furnishing characters sufficiently obvious and precise to warrant such arrangement.

2. *Terebratula*. The muscular peduncle of this genus passes through a perforation in the largest valve. The arms are shorter than those of lingula, and forked at the extremities. They are supported within by numerous arcuated plates.

There is one recent species described in the article Conchology, vol. vii. p. 36, genus xxxix. and figured tab. ccvi. fig. 2, as *T. vitrea*. It appears, however, to be the *T. cranium* of Muller, figured in *Zoologia Danica*, tab. xciv. f. 1. Although we can boast of only one recent species of this genus, our rocks abound in many others which are extinct. Mr. Sowerby, in his valuable work, *Mineral Conchology*, now publishing, has given excellent representations of several of these. He has been able, from an attentive examination of their form, to construct several new genera, and, from a dissection of the cavity, to unfold the remains of the spiral arms.

3. *Criopus*. In this genus, first instituted by Poli, one of the valves is membranaceous and flat, and adheres to stones, and the other is flatly conical, and resembles a Patella. The arms nearly resemble those of Lingula. The ovarium, according to Muller, is double and branched, and the eggs are round.

The *Criopus anomalus* is described and figured by Muller under the name Patella anomala, in the *Zoologia Danica*, tab. v. f. 1—8, and by us, for the first time, as a native of Britain, in the article Conchology, vol. vii. p. 65, genus i. sp. 7, P. distorta, tab. cciv. fig. 4.

It is to be regretted, that so little progress has been made in the examination of the animals of this class. We are still ignorant of their nervous system, and their mode of propagation; and when these and their other organs shall be more carefully investigated, many new divisions will probably be necessary, as the species increase in number.

Class VII.—CIRRHIPODA.

The genus Lepas of the Linnean system, after having been subdivided into different genera, has at length, by the efforts of M. Lamarck, been formed into a distinct class. The animals which it includes are protected by a cloak, strengthened by testaceous plates, to which the body adheres by one or more muscles. The head consists of a slight eminence attached to the anterior portion of the body, and, when in the natural position, near the inferior margin. The body is followed by a tail, supporting six feet on both sides, each of which consists of a short stem, which divides into two tapering jointed fringed filaments; these, by their motion towards the mouth, bring the water and its contents within the sphere of that organ. The tail terminates in a conical tubular body, which has improperly been termed a proboscis.

The nervous system consists of a cord encircling the gullet, and giving out filaments to the mouth; its two ends running along the belly and tail, and uniting at the base of each pair of feet to form a ganglion, and give off filaments.

The mouth is furnished with an obvious upper lip, a pair of maxillæ on each side, with the rudiments of palpi. Ellis says, "the mouth appears like that of a contracted purse, and is placed in front between the fore claws. In the folds of this membranous substance are six or eight horny laminæ, or teeth, standing erect, each having a tendon proper to direct its own motion. Some of these teeth are serrated, others have tufts of sharp hairs instead of indentations on the convex side, that point down into the mouth; so that no animalcule that becomes their prey can escape back." The gullet is very short, and enters into a stomach, having two cæca and glandular walls, which serve as a liver. The intestine is short and simple, and terminates behind at the base of the caudal appendage. There are two salivary glands attached to the stomach. The gills are conical bodies, situated at the base of the feet. The organs of circulation are imperfectly understood. Poli observed the motion of the heart, but the vessels which are connected with it are unknown.

The organs of reproduction appear, according to Cuvier, to consist of an ovarium giving out an oviduct, which traverses a body considered as a testicle, and both the canals unite in a common tube, which traverses the caudal appendage, and opens by a small pore at its extremity. This aperture Cuvier regards as simple, but Ellis observes of the whole, "it is of a tubular figure, transparent, composed of rings lessening gradually to the extremity, where it is surrounded with a circle of small bristles, which likewise are moveable at the will of the animal. These, with other small hairs on the trunk, disappear when it dies." There is probably no union of individuals, each being perfect hermaphrodites.

The rapidity of growth which these animals exhibit is truly astonishing. A ship's bottom becomes covered with them in a few months, and the spawn of some kinds deposited on a feather, as stated in the memoirs of the Wernerian Society, vol. ii. p. 243, will become unfolded, and attain maturity before the feather exhibits any symptoms of decay.

The animals of this class are all inhabitants of the sea, and are all fixed to other bodies. Many of them, however, are attached to floating wood, and others to the skin of marine animals, so that they enjoy all the advantagers of locomotion without the exercise of the exertion requisite for its production. Their remains are seldom found in a fossil state. Some of the species have been used as food. In taking a view of the genera we shall distribute them, as formerly, after the manner of Ellis, *Phil. Trans.* vol. l. p. 848, into pedunculated and sessile.

Order I. Pedunculated.

The essential character of this order consists in the body being supported by a peduncle, the lower part of which is permanently fixed to other bodies.

The cloak consists of three membranes. The external one is the cuticle, and invests the whole external surface of the animal. Underneath this is the true skin, in which are formed the testaceous plates that protect the body. These plates or valves are evidently formed in the same manner as common shell, the layers of growth being indicated by the striæ on the surface. The inner membrane forms a sac for the body itself. This bag is closed on all sides except opposite to the tail, where there is a slit, through which the feet are protruded.

The peduncle consists of the two external membranes of the integuments of the body. The cuticle covers its surface, and even the base by which it adheres. The true skin is covered on its central aspect with numerous muscular threads. The summit of the peduncle next the body is covered with the inner membrane of the cloak, through which, however, there is a perforation, corresponding to a large vessel which descends along one of the sides of its central cavity. This cavity, in the *Lepas anatifera*, Cuvier found filled with a white cellular substance soaked with muscus. Ellis, on the other hand, found the peduncle of what has usually been regarded as the L. aurita "full of a soft spongy yellow substance, which appeared, when magnified, to consist of regular oval figures, connected together by many small fibres, and no doubt are the spawn of this animal." This view of the subject entertained by Ellis may, upon investigation, lead to the conclusion, that the cavity of the peduncle and its lateral vessel are connect with the reproductive organs. It would be desirable to have the branched peduncles dissected with care, as a knowledge of their structure might throw some light on the mode of growth of these animals.

1. *Family.* This group is characterized by the body being protected by five testaceous plates, and by the peduncle being naked. It includes the following genera.

1. *Lepas.* The two lateral plates at the summit of the shell are very large, nearly covering the whole of the compressed body, and having attached to it the large adductor muscle. The two valves which protect the sides of the tail are much smaller, and somewhat triangular, while the dorsal one is narrow and convex externally. The branchiæ are four in number, two on each side of the body, near the origin of the first pair of feet. The British species are four in number, *L. anatifera*, *anserifera*, *sulcata*, and *fascicularis*.

2. *Otion.* This genus was instituted by our zealous and intelligent friend Dr. Leach, whose labours have greatly contributed to improve the classification of the genera of this class. The body is but slightly compressed, and the valves are very small and distant from one another, the body being chiefly covered by its membranaceous cloak. The inferior part of the cloak terminates in two tubular appendages, through which the water escapes which has been taken in at the oral aperture, and has passed along the surface of the gills. The gills are sixteen in number, eight on each side. The first pair on each side resembles those of the Lepas, the remaining six are attached to the base of the feet. There are two British species. 1. *O. aurita*, Cuvier, *Mem. des Anatifes.* Fig. 12, 13. A specimen of this was found on the Dawlish coast, Devon, by Mr. Comyns. 2. *O. cornuta*, taken alive from the bottom of a transport stranded on the coast of Devon, by Montagu, and described and figured by him, *Linn. Trans.* vol. xi. p. 179, tab. xii. f. 1.

3. *Cineras.* This genus was likewise instituted by Dr. Leach. The valves are equally minute and remote as in the preceding genus, but there is here no appearance of tubular appendages to the cloak. The *C. membranacea*, first described and figured by Montagu, *Linn. Trans.* vol. xi. p. 182, tab. xii. f. 2. is the only species known to inhabit the British seas.

2. *Family.* In this family the testaceous valves are numerous, greatly exceeding five. It consists of two genera.

1. *Scalpellum.* The testaceous valves are thirteen in number, and invest the body. The peduncle is covered with corneous wrinkles, having hairy interstices. The S. vulgare, the *Lepas scalpellum* of British authors, is the type of the genus.

2. *Pollicipes.* The testaceous valves are ten in number, with numerous scales investing the base of the peduncle near the body. The *P. vulgaris*, or *Lepas pollicepis*, is the type of the genus.

II. Order. Sessile.

In this order the body adheres directly to foreign substances, without the intervention of a tubular stalk. The adhesion is effected in some by the coriaceous cloak, in others by a layer of testaceous matter. The testaceous covering usually assumes a conical form, the base being attached to rocks or other substances, and the apex truncated and open, as an entrance for the water. This cone consists of six valves, closely connected together, but capable of being disjoined by maceration, especially when young. In old shells, where the valves have attained their full growth, they appear to become cemented together, so that it is very difficult to effect their separation. The valves are so arranged, that one protects the belly, another the back, and two on each side the lateral parts. In some genera, all these valves are so united, that the lines of separation are not perceptible, while in others the double lateral valves only are incorporated. Each valve consists of an elevated and depressed portion. The elevated portion is conical, with its base at the adhering part of the shell, while the depressed part of the same form has the base at the mouth. The former consists of conical vertical tubuli, while the latter appears solid. When the base is testaceous, it is either solid, or consists of horizontal tubuli, radiating from a centre united by a simple layer, exhibiting concentric circles.

The structure of the valves gives sufficient indications of the manner in which they are formed. M. Dufresne, in a paper published in the *Annales du Museum* 1. p. 465, advanced the singular opinion, that the animals quitted their old shells when they became too small, and formed new ones suited to their size. The arguments by which it is supported indicate an ignorance of the structure of the shell, and the relations of the parts of which it consists. To us it appears plain, that each valve is increased in two directions, the elevated part by an extension of the tubuli at the base, and the depressed part by the application of fresh matter to the side. The striæ, which are the indications of successive depositions of matter, and the structure of the valves themselves, point out this mode of enlargement as the only one which can take place, even on the supposition that the shell is frequently renewed. By the growth of the elevated parts, the shell increases in height and diameter at the base, while the growth of the depressed parts preserves to the mouth suitable dimensions for the corresponding increase of size in the parts of the operculum. It is obvious that this increase of diameter at the base must be accompanied by a corresponding enlargement of its covering. This takes place by the extension of the horizontal tubuli, and each enlargement is marked by a concentric ridge.

This opinion which we have espoused, and which we find hinted at by Lamarck, in his "*Histoire Naturelle des Animaux sans Vertebres*," v. p. 398, is founded on the structure of the different valves, the indications of the layers of growth, and the manner in which the valves are separable from each other and from the base. We might have entertained some suspicions of error, had we not attended to the morbid appearances of the shell, the restraints imposed on its growth by the situation in which it lives, but especially the manner in which fractures are healed, and abstracted parts restored by the secretion of new matter. Such observations have removed all suspicion, and demonstrated the truth of the explanation offered. It may be added, however, that, in the case of the inversely conical shells, the increase probably takes place at the mouth.

The mouth of the shell is closed by the cloak of the animal, leaving in the centre a tubular or linear aperture for the protrusion of the feet and entrance of the water. This part of the cloak is protected by testaceous plates, which, by their union, form a lid to the mouth of the shell, for the protection of the contained inhabitant. The valves of the lid are four in number, two on each side the mesial line, or orifice. In some genera the lateral valves are united. The operculum of this order may with propriety be compared to the shelly plates of the body of the preceding order—and the shelly body of this order corresponds to their peduncle, circumstances indicated by the muscular attachments of the animal. The continued action of the valves of the lid obviously assist in wearing down and enlarging the aperture of the shell.

There is little known, either with regard to the organs of digestion or respiration, in the animals of this order. In their manner of reproduction, they appear to resemble those of the preceding order. Ellis "found the lower part of the shell, which contained a cavity equal to two-thirds of the whole, full of spawn." The genera of this order divide themselves into three families, from circumstances connected with the shell.

1. *Family*.—The shell in this family consists of six valves, and the lateral valves of the lid are divided. It contains five genera.

1. *Tubicinella*.—The form of the shell in this genus is inversely conical, the apex which constitutes the base being truncated. It consists of a series of horizontal rings, which mark the successive periods of growth, and there are six vertical grooves, which indicate the divisions of the valves. The increase of the shell with age, in this genus, probably takes place by the addition of a new ring to the mouth. The testaceous plates of the lid are all of equal size. The inferior aperture of the shell is open, or simply closed by the integuments of the cloak. The animal resides in the skin of the whale, the lower rings being inserted in the fat, while one or more of the upper ones appear above the cuticle. The T. *balænarum* is the only known species.

In the remaining genera of this family, and the others which follow, the shell is conical, its truncated apex being the mouth; and its mode of growth such as is detailed in the general remarks on the order.

2. *Coronula*. The base of the shell is open, as in the preceding genus. The valves of the lid are unequal in size, the dorsal ones being small. The animals included under this genus likewise inhabit the skin of the whale. Several species of this genus are known. The C. *diadema* holds a place in the British Fauna.

3. *Chelonobia*.—In this genus the base of the shell is likewise open, but it differs from the preceding in the plates of the lid being all of equal size. The C. *testudinaria*, a species which resides on turtles, is the type of the genus.

4. *Balanus*. The shell in this genus is closed below by a layer of shelly matter, which adheres to foreign bodies, and conforms to the inequalities of their surface. Nine species are described as natives of Britain.

5. *Acasta*. In this genus the base of the shell is cup-shaped. The species reside in sponges, in the substance of which the base and sides are imbedded. One species, the *Balanus spongiosus* of Montagu, is a native of the English seas.

2. *Family*. The valves of the shell in the genera of this family are only four in number.

1. *Creusia*.—The base in this genus is funnel-shaped. The lateral valves of the lid are united. The C. *spinulosa* of Dr. Leach is the type of the genus. It is imbedded in the substance of Madrepores.

2. *Conia*.—The shelly base in this genus conforms to the substance to which it is attached. The lateral valves of the lid are separate. The C. *porosa* is the type of the genus.

3. *Clisia*.—The base of the shell is spread on the surface of the bodies to which it it attached. The lateral valves of the lid are united. The Balanus stratus of British writers is the type of the genus. An imperfect representation of the animal is given by Cordiner, in his "*Remarkable Ruins*," table, Aggregate of Corals.

3. *Family*. The shell is undivided in the only genus of this family which is known, termed *Pyrgoma*. The base is cup-shaped, and the lateral valves of the lid are separate.

Although we have introduced this class to the notice of our readers under the article Mollusca, we are nevertheless of opinion, that it is more nearly related to the annulose animals. The appearance of the nervous system, and the structure of the mouth and of the tail, intimate its connection with the crustacea, and justify the appellation *Crustacea conchilifera*, by which Lamarck intended at first that it should be designated.

We shall now conclude this article by a list of figures of a few of the species in the different classes, illustrative of the forms which they exhibit. The reader will find in Plates CCCXCVIII. and CCCXCIX. Fig 1. Ocythöe cranchii. Fig. 2. Two of the corneous rings of the suckers of Loligo sagittata. Fig. 3. Mandibles of ditto, a, the under one, b, the upper one. Fig. 4. Pneumodermon, peronii. Fig. 5. Testacella haliotoidea. Fig. 6. Onchidium typha. Fig. 7. Doris marginata. Fig. 8. Thethys fimbria. Fig. 9. Phyllidia ocellata. upper side. Fig. 10. Phyllidia trilineata, under side. Fig. 11. Pleurobranchus membranaceus. Fig. 12. Bulla hydatis. Fig. 13. Valvata cristata, magnified. Fig. 14. Buccinum undatum, without the shell. Fig. 15. Hyliotis tuberculata. Fig. 16. Modiolus vulgaris. Fig. 17. Synoicum turgens. Fig. 18. Lingula unguis. Fig. 19. Tubicinella balænarum. Fig. 20. Coronula balænaris.

(J. F.)

MOLUCCAS, or Spice Islands, comprehends, in the most extensive sense of the term, all the islands between Celebes and New Guinea, situated to the east of the Molucca passage, in longitude 126°, particularly those of Gilolo; but, in a more limited sense, it is usually restricted to the Dutch Spice Islands, Amboyna, Banda, Batchian, Ceram, Ternate, Tidore, &c. These islands (the chief of which will be found described under their respective names in this work,) were first discovered by the Portuguese in 1510, but afterwards fell into the hands of the Spaniards, who were supplanted in their turn by the Dutch in 1627. The climate of these islands is generally moist and unhealthy. Their principal productions are, cocoa-nuts, rice, sago, cloves, ginger, mace, nutmegs, with several herbs and plants. No metals are found upon them, but pearls are said to be frequently met with on their coasts. Goats are the most common animals on these islands, and snakes of various descriptions. But the birds of paradise, which are supposed to come from New Guinea, are taken in great numbers on the Moluccas, by means of bird-lime, and form a considerable article of traffic. At the discovery of these islands, two distinct races of people were found upon them, the Malays, or Mahommedans, on the sea-coast, and the oriental negroes, or Papuas, in the interior. The former speak a dialect of the Malay tongue, mixed with many foreign words; but the ancient Molucca or Tirnata language appeared to Dr. Leyden to have been an original tongue. They have adopted many of the tenets, or rather observances, of the Brahminical system, but many of them, named Shereefs, boast of their descent from Mahommed, and are held in great respect, especially if they have performed the pilgrimage to Mecca. The Papuas have been rapidly decreasing, and have wholly disappeared in most of the smaller islands. But they still exist in many of the more eastern islands, and hold undisturbed possession of New Guinea. The houses on these islands are generally raised on pillars 8 or 10 feet high, on account of the moisture, and are entered by means of a ladder, which is afterwards drawn up. The colour of the natives is a deep mixture of black and yellow, and their dispositions wild and ferocious. They subsist chiefly on sago. The men wear little covering, except a hat of leaves, and a piece of cloth round their middle; and the women are dressed in a large wide garment like a sack, with a remarkably broad hat on their heads. Their arms are a kind of light tough wood, arrows of reed, pointed with hard wood, and bucklers of black hard wood, ornamented with designs in relievo, made with beautiful white shells. They excel in the construction and management of their vessels, which resemble in great measure those which have been already described under the article Magindanao. See Sonnerat's *Voyage to the Spice Islands;* and Forrest's *Voyage to New Guinea.* (*q*)

MOLTON, South, a town of England, in Devonshire, is situated on an eminence on the western bank of the River Moult. The town consists of three streets, meeting at the market place, where the houses are large and neat. The public buildings are, the church, which is handsome and spacious, and the town-house. There is here a Free School, founded in 1614. Serges, shalloons, and felts, were manufactured here. The population of the parish, in 1811, was 555 families, and 2739 inhabitants. See the *Beauties of England and Wales*, vol. iv. p. 276.

MONAGHAN, an inland county in Ireland, in the province of Ulster, is bounded on the north by Armagh and Tyrone; on the east by the former county and Louth; on the south by Cavan and Louth, and on the west by Fermanagh. It is the smallest county in the province of Ulster, and indeed in all Ireland, with the exception of four counties in Leinster, viz. Louth, Dublin, Carlow, and Longford. The county of Armagh approaches nearest it in size, Monaghan, according to the best authorities, containing 179,600 Irish acres, and Armagh 181,450. It is divided into five baronies, Monaghan, Cremowine, Dartrey, Freugh, and Farney: the last is sometimes called Donaghmoyne. The number of parishes is 19. The principal towns are, Monaghan, Castle Blaney, Carrickmacross and Clones; but they are all poor and small places. Its length is about 30 miles, and its breadth 22. It is in the diocese of Clogher, and province of Armagh; and returns two members to Parliament. Monaghan is one of the most uninteresting and unimportant counties of Ireland, in almost every point of view—our notice of it, therefore, will be brief. Its surface is not mountainous, but in most parts is occupied by a number of hills, scattered in an irregular manner, without forming continued ridges or chains. On the borders of Tyrone and Armagh, however, these hills rise in height, and are more connected, partaking of the character of the adjacent Few mountains. In the interior of the county there are a number of bogs; but in some places these have been drained with great skill and labour, and at considerable expense; or, where they could not be drained, have been converted into sheets of water, which greatly add to the appearance of the county. The soil in general is cold and poor, but in some parts naturally rich. This character particularly applies to what is called the Mountain of Criene, an elevated tract of land, intersecting the centre of the county, the soil of which is a rich loam on limestone gravel. This tract is also rendered more fertile as well as picturesque by a number of small streams which flow through it. With the exception of a few spots, there is little or no wood; and this bareness is not compensated by field-enclosures, as the corn-fields are in general naked, and without hedge-rows.

There are no lakes of any size or beauty; and the only river of the least consequence is the Fener, which rises in the west of the county, and falls into Loch Earne. There are said to be some appearances of lead, iron, and other minerals; but if there are, they are neglected. Limestone, marl, and freestone, however, abound; there are some large quarries of the last in the hills on the borders of Tyrone; and on Cairnmore, the highest of these, excellent millstones are procured. The climate of Monaghan is cold and ungenial.

The agriculture of this county is in a very poor and depressed state. The largest property amounts to 33,000 acres; but in general the estates are small. Many of them are held under the Crown, since the Scotch colony was introduced here; and many small portions of land, some of which do not yield above 20*l.* annual income, are possessed by the descendants of Cromwell's soldiers. Nearly the whole of the land in the county is divided into very small tenures, called in Ireland *holdings.* The number of forty-shilling freeholders, according to the last returns to Parliament, was 5521; of 20*l.* 146; and of 50*l.* and upwards, 172. Few of the farms on the larger estates are let in perpetuity; the more general term is 21 years and a life, or three lives.

According to Sir Charles Coote, in his Survey of this county, the leased farms are under an average of ten acres; taking the large farms, they would not average 25; and as the small ones, which are far more numerous, do not average six, ten may be the mean rate of the whole county. From this account of the size of the farms, it will naturally be concluded that they are entirely arable, and that the agriculture practised on them cannot be good. A great part of the ground is dug with the spade, or, where a plough is used, it is the joint contribution of three or four farmers, one bringing the implement itself, another a horse or bullock, or even a milch cow, and a third attending himself. Many *holdings* are too small to maintain a family. Some only possess a *dry cot*, that is, a house without land; these purchase every year an acre or two of grass for their cow and horse, and *corn acres*, or ground for potatoes and oats. Yet even these poor creatures pay a high rent, from a guinea and a half to two guineas an acre. Flax, potatoes, and oats, are almost the whole produce of the soil: according to the statistical survey, the whole county has seldom 100 acres of wheat. Some bear, or bigg, (a coarse species of barley) is grown, and in a few rich spots barley is cultivated. The farmers, however, do not depend on these crops, but entirely on their flax, potatoes and oats. The pasture husbandry of this county is on a very limited scale, and not well managed: most of the small farmers keep one or two cows, and make butter; the principal markets for it are Monaghan and Newry. One cow is generally kept on every five acres; and one hundred weight of butter, per cow, is considered the usual produce. The stock consists of the small stunted breed, still so common in Ireland. Scarcely any sheep are kept: goats are numerous, and are found round the greater part of the cabins, many of the poorer families being supplied with the milk they use by this animal. Many hogs are kept; Carrickmacross is a great market for them.

The only manufacture in Monaghan is that of linen; and for it this county is rather celebrated. The inhabitants are chiefly weavers, as well as farmers; women hire themselves out to spin the yarn: their wages are 3*l.* 10s. or 4*l.* per annum, besides their board and lodging; if they spin at their own houses, they earn about three shillings a week. It requires about three weeks to weave a web of 25 yards; the average pay is 1*l.*; hence it appears that the weekly wages of a weaver is about 6s. 8d. The consumption of a manufacturing family, consisting of six individuals, is estimated at 5s. a week; their food being potatoes, herrings, and buttermilk: the weekly expense of an agricultural family, of the same number, is 7s. 6d. as they will occasionally use oat-meal, milk, and pork. The principal markets for the linens within the county are, Monaghan, Castle Blaney, and Carrickmacross. The linen trade of this county is averaged at about 200,000*l.* a year.

The catholics in this county are as five to one compared with the protestants; the latter are chiefly presbyterians. In the year 1792, there were 21,523 houses, and 118,000 inhabitants, in this county; on the supposition that there are 280 square miles, there will be 76.86 inhabitants to a square mile; and on the supposition that there are 179,600 acres, there will be 83 acres to each house. The state of the peasantry, from what has already been mentioned, it may be conceived, is wretched; and yet there are parts of the county where improvements are going on, and civilization is advancing. As a proof of the poverty of Monaghan, it may be stated, that, though the smallest county in Ulster, it contains more houses with only one hearth than any of the other counties, except Antrim, Armagh, Tyrone and Down; whereas Londonderry, which contains twice the number of acres, has only one half the number of one-hearth houses.

Monaghan has scarcely any antiquities, except a round tower, and two of those *raths* called Danish forts, at Clones. This place was formerly the seat of an episcopal see, and a borough; in the ruins of the abbey burial ground are several magnificent tombs. See Sir Charles Coote's *Survey of Monaghan*; Wakefield's *Ireland*; Dr. Beaufort's *Memoir of a Map of Ireland*. (w. s.)

MONACHISM. The origin of Monachism cannot be traced higher than the middle of the third century of the Christian era, though Roman Catholic writers have erroneously and unsuccessfully endeavoured to prove, that the Ascetics, who were not uncommon long before this period, were monks. The monastic state originated in the last: the first monk whose name has reached us is St. Paul, usually styled the hermit; he retired into upper Egypt in 250, and after having attained the extraordinary age of 113 years, died in 341. Nearly about the same period, Anthony, a young man of very moderate attainments in literature, but evidently possessed of a strong understanding, who was born in the lower parts of the Thebais, and possessed a small tract of very fertile land in that part of Egypt, sold his property, distributed it among his relations—and, leaving his home, retired at first among the ruins of the tombs—afterwards to a lonely, but shady and well watered spot in the desert, and ultimately fixed his residence on a hill near the Red Sea. He also lived to the very advanced age of 105, and before his death, a numerous body of men lived in community with him, and led, under his guidance and example, a life of *piety* and manual labour. Perhaps, therefore, he may more properly than Paul be regarded as the first monk, since he undoubtedly first established a monastery.

The first written rule for the conduct of the monks was composed by Pachomius, who lived in the reign of Constantine: Pachomius, with 1400 of his brethren, occupied the isle of Tabenne, in the Nile, and founded, besides, nine monasteries of men, and one of women: according to other accounts, the Isle of Tabenne contained about 13 monasteries; 30 or 40 monks occupied one house: 30 or 40 having composed a monastery; a Dean was placed over every 10 monks; a superior over every house; every monastery had its abbot; and a general director superintended all. All the monks met every Sunday at the general oratory of the monastery; and Easter was occasionally celebrated by the monks of all the communities, amounting to nearly 50,000, assembling in one body. The same mistaken views of religion which introduced and established monachism, induced some of the monks to aim at a still more retired mode of life, and what was deemed a higher degree of perfection. Hence, the monks were divided into two classes, the Cænobites, who lived in community, and the Anchorites, who lived in separate cells. Between these extremes, there seems to have been a third kind of establishment of monks; each separate cell of the Anchorites was surrounded by an enclosure, and their general precinct was called a Laura.

Besides these sects of monks, who renounced the world, and lived in perpetual celibacy, there was another order, which, however, was never numerous, who lived in a married state, and enjoyed their own property and possessions. Originally all monks were laymen: The council of Chalcedon expressly distinguishes them from the clergy, and ranks them with laymen; and it was not till the time of Clement V., A. D. 1311, that monks were obliged to take holy orders, that they might say private mass for the honour of God.

Anthony had enjoyed the friendship of Athanasius; and the latter introduced into Rome the knowledge and practice of the monastic life, about the year A. D. 341. At first, the uncouth and savage appearance of the Egyptian monks, whom Athanasius brought for the purpose of initiating the Romans, excited disgust and laughter: but these feelings soon gave way to an enthusiastic admiration of the new sect, and senators and matrons transformed their palaces and country seats into religious houses. About the same time monachism was introduced into Palestine, by Hilarian, and into Pontus, by Basil. In the year A. D. 370, Martin, "a soldier, an hermit, a bishop, and a saint," erected the first monastery in Gaul; his funeral is said to have been attended by 2000 of his disciples.

In the 6th century, a new order of monks arose, which reached a greater degree of influence and celebrity than any which had preceded it. St. Benedict, an Italian monk, was its founder; his religious rules were at first intended and framed merely for the government of a convent at Mount Cassino, between Rome and Naples, over which he presided, but it afterwards was adopted by, or forced upon, a very great number of monasteries. His rule was founded on that of Pachomius, though in many respects it deviated from it. His great object seems to have been, to render the discipline of the monks milder, their establishment more solid, and their manners more regular than those of other monastic establishments. The whole time of the monks of his order he directed to be divided between prayer, reading, the education of youth, and other pious and learned labours. All who entered his order were obliged to promise when they were received as noviciates, and to repeat their promise when they were admitted as full members of the society, that they would in no respect, and on no account, attempt to change or add to the rules which he had instituted. His rule was embraced by all the monks of the west. Benedict admitted both the learned and unlearned into his order; it was the duty of the first to assist at the choir; of the latter to attend to the household economy, and temporal concerns of the monastery. At this period, it may be observed, that the recitation of the divine office at the choir, (as it is called by the Catholics,) was confined to the monks; afterwards it was established as the duty of all priests, deacons, and sub-deacons. The Benedictines at first admitted none into their order, who were not well instructed how to perform it; but it was not necessary that they should be priests, or even in holy orders. Afterwards, many were admitted into the Benedictine order, who were ignorant of the duty of the choir; those were employed in menial duties: Hence the introduction of *Lay Brothers* into the Benedictine order. When first introduced, they were not considered as a portion of the monastic establishment, but as merely attached and subordinate to it; but, in course of time, both the order and the church acknowledged them to be, in the strictest sense of the word, professed religious. All other religious orders, both men and women, following the example of the Benedictines, have admitted lay brothers and sisters. In 1322, the council of Vienne ordered all monks to enter into the order of priesthood. The monks of Vallombrosa, in Tuscany, are the first among whom lay brothers are found under that appellation.

The irruption of the Lombards into Italy, and of the Saracens into Spain, and the civil wars in France after the death of Charlemagne, having introduced great disorder among the Benedictines, they were reformed by St. Odo, in his monastery at Cluni; and several monasteries adopted this reform. In the eleventh century, the Benedictine order again fell from its original purity and strictness. This gave rise to many attempts to restore it to its pristine form and object: Hence arose the Carthusians, the Camadules, the Celestines, the monks of Grandmont, the Congregation of St. Maur, and the celebrated monks of La Trappe.

In the eighth century, a kind of middle order between the monks and the clergy was formed; they were called the canons regular of St. Augustine; their dwellings and table were in common, and they assembled at fixed hours for the divine service; in these respects they resembled the monks; but they differed from them in taking no vows; and they often officiated in churches committed to their care. Having degenerated in the twelfth century, Pope Nicholas II. introduced a considerable reformation among them. At this period, they seem to have divided into several branches of the original order; some formed themselves into communities, in which there was a common dwelling and table, but each monk, after contributing to the general stock, employed the fruits of his benefices as he deemed proper. At the head of another sect was the Bishop of Chartres; he adopted a more rigid and austere mode of life. This sect renounced their worldly possessions, all private property, and lived exactly as the strictest order of monks did. This gave rise to the distinction between the *secular and regular canons*. The former observed the decree of Pope Nicholas II. the latter followed the Bishop of Chartres; they were called the regular canons of St. Augustine, because they were formed on the rules laid down by St. Augustine in his Epistles. They kept public schools for the instruction of youth, and exercised a variety of other employments useful to the Church. A reform was effected in the Augustines by St. Norbert; and as he presided over a convent at Primontre in Picardy, those monks who adopted his rule were called Primonstrabenses. They spread throughout Europe with great rapidity.

During this period convents of nuns were established, the institutes and regulations of which were similar to those adopted by the Benedictines and Augustines, or to the reformed branches springing from those two great orders.

Till the thirteenth century, these were the only orders of monks; at that period the mendicant orders arose: those were, the Franciscans, Dominicans, Carmelites, and the Hermits of St. Augustine. The establishments of the Mendicants seem to have been necessary, as the other monks had greatly degenerated; they were rich and indolent, and consequently totally unfit for the objects for which they were instructed. Innocent III. was the first Pope who perceived the necessity of instituting an order, who, "by the austerity of their manners, their contempt of riches, and the external gravity and sanctity of their conduct and manners," might rescue the church from the reproach which the monks had brought upon it.

The Franciscans were founded by St. Francis; he was the son of a merchant, but, as was usual in those times, he possessed little or no learning; the brethren of his order were called Friars, minors, or the little brethren. They chiefly were engaged in the more laborious parts of religion, in hospitals, in prisons, among the lower orders of the poor; in short, where danger, labour, or other causes kept away the Benedictines and Augustines, there they were to be found; where there was no hopes of remuneration, the Franciscan friars were sure to be found. Many of them were eminent for their learning, and some have been Popes.

Soon after the death of their founder, they were divided into three orders; the Conventual friars, who admitted some relaxation into their original rule; the Observantine friars, who observed the rule more strictly. In France, these were called Cordeliers, from the cord with which they fastened their habit; from the Observantines sprung the Recollects, or Grey-friars, and the Capuchins, so called from a patch worn by them on the back of their habits. The Conventual and the Observantine friars formed the first of the three orders, into which the followers of St. Francis were divided. The second order was remarkable for its extreme severity, and was called the order of the Poor Classes. The third order embraced persons of both sexes; they lived in the world, but were united by certain rules; this order was imitated by the Dominicans and Carmelites.

The Dominicans derived their name from St. Dominic; at first he adopted the rule of the Canons' regular of St. Augustine; afterwards he adopted that of St. Benedict; but the alterations and additions he introduced made it almost an entirely new rule. In a chapter of his order at Bologna in 1220, he obliged the brethren to take a vow of absolute poverty, and to abandon entirely all their revenues and possessions. The Dominicans were first called preaching friars, because public instruction was the chief object of their institution. In England they were called black friars. "During three centuries the Franciscans and Dominicans governed, with an almost absolute and universal sway, both state and church, filled the most eminent posts, both ecclesiastical and civil, taught in the universities and churches with an authority, before which all opposition was silent, and maintained the pretended majesty and prerogatives of the Roman pontiffs against kings, princes, bishops, and heretics, with incredible ardour and equal success. These two celebrated orders restored the church from that declining condition in which it had been languishing for many years, by the zeal and activity with which they set themselves to discover and extirpate heretics, to undertake various negotiations and embassies for the interests of the hierarchy, and to confirm the wavering multitude in their implicit obedience to the Roman Pontiffs." The Carmelite order was originally instituted in Palestine, whence in the thirteenth century it was brought into Europe. A reform was introduced with this order by St. Theresa; the reformed, from their not wearing shoes, were called the unshodden Carmelites. Pope Alexander IV. observing that the Hermits were divided into many classes, some following the maxims of Augustine, formed the design of uniting them into one religious order, and prescribed a rule for their government; hence originated the Mendicant order of the Hermits of Augustine. These, however, as well as the Carmelites, were very inferior in number, reputation and influence, to the Franciscans and Dominicans. The public attachment to all these mendicant orders was so strong and prevalent, that several cities were divided into four parts, for these four orders; the Dominicans had the first part, the Franciscans the second, the Carmelites the third, and the Hermits of Augustine the fourth; from no others except one of these orders would the people receive the sacrament, and the churches in which they preached were regularly and constantly filled. The appellation of Friars, given to all these orders, whereas that of monks was given to those which existed before them, points out the distinction between the meaning of these two appellations, which are often confounded; the monks never travelled through the country, and indeed never left their monasteries; the friars, on the contrary, spent their time for the most part in travelling.

We are informed by excellent authority, Mr. Charles Butler, that these "four orders are the only orders which the church has acknowledged to be Mendicant. An order is considered to be Mendicant, in the proper import of that word, when it has no fixed income, and derives its whole subsistence from casual and uncertain bounty, obtained by personal mendicity. To that St. Francis did not wish his brethren to have recourse, till they had endeavoured to earn a competent subsistence by labour, and found their earnings insufficient. But soon after the decease of St. Francis, the exertions, equally incessant and laborious, of his disciples, for the spiritual welfare of the faithful, appeared, in the universal opinion of the church, to be both incompatible with manual labour, and much more than a compensation to the public for all they could possibly obtain from it by mendicity. This opinion was unequivocally expressed by St. Thomas Aquinas, and sanctioned by a bull of Pope Nicholas III.; since that time the friars did not use manual labour as a means of subsistence, but resorted in the first instance to mendicity." Mendicity seems to have made no part of the original rules of the Dominicans, Carmelites, or Hermits of Augustine: and in consequence of the evils attendant on it, the Council of Trent confined mendicity to the Observantines and Capuchins, allowing the other Franciscan establishments, and almost all the establishments of the three other orders, to acquire permanent property.

In consequence of the progress of the Reformation, and the loss of influence and authority which the Franciscans and Dominicans had sustained, partly from this event, and partly from their own relaxation and misconduct, the Pope was extremely desirous of establishing a new order, which should fill their place, discharge their duty, and zealously oppose the Protestants. At this period, 1534, appeared Ignatius Loyola, a Spanish knight, originally an illiterate soldier, and then a fanatic of most wonderful zeal and talents. In this year he, with ten of his Capuchins, laid the foundation of the Society of Jesus, by the vow which they took in the chapel of Montmartre, near Paris. In 1540 and 1543, his Institute was approved by Pope Paul III. The Society of Jesus, or the Jesuits, as they are generally called, hold a middle rank between monks and the secular clerks, approaching nearer to the regular canons than to any other order; they lived separate from the multitude, and were bound by religious vows; but they were exempt from stated hours of worship, and other strict observances, by which the monks were bound. Their principal duty was to direct the education of of youth, and the consciences of the faithful, and to uphold the cause of the church by their missions, and their pious and learned labours. They were divided into three classes; the first of which were the professed members. These, besides, the ordinary vows of poverty, chastity, and obedience, bound themselves to go, without murmur, inquiry, deliberation, or delay, wherever the Pope should think fit to send them; they were Memdicants without property. The second class comprehended the scholars; these were possessed of large revenues; their duty was to teach in the colleges of the order. The third class comprehended the novices, who lived in the houses of probation. The secrets of the society were revealed only to a few even of the professed members. In the year 1776, Clement IV. suppressed the Jesuits; the society, however, was restored in 1814 by a papal bull.

As the Reformation begun by Luther was mainly occasioned by the gross abuse of monastic establishments; so in its earliest stages it brought about their fall in all countries which embraced the Protestant religion. Henry VIII. of England eagerly seized the opportunity of enriching himself and his favourites by the dissolution of abbeys, monasteries, convents, and all other Catholic establishments; the monasteries, of different ranks and classes, suppressed, amounted to 3182. Their annual revenue was estimated at the enormous sum (for those days) of 140,784*l.*; and the persons they contained are supposed to have amounted in number to about 50,000. Monasteries continued in the Catholic countries till the French Revolution swept them away in France, and the other countries in which the French gained an absolute sway, and greatly reduced their splendour and power in all the other countries into which the French army penetrated. At present they are partially restored; but their discipline and power are comparatively very low, and more in conformity to the failings of human nature, as well as to the spirit and real interests of religion. Having thus given a sketch of the origin and history of the rise of monachism, and of the different kinds of monks and friars, we shall now proceed to describe the laws and rules that relate to the monastic life, as they respect their dress, diet, manual labour, vows, superintendants, and different officers, &c.

I. On their admission the monks were obliged to change their dress. According to the original rule of Benedict, his disciples were at liberty to adopt the coarse and usual dress of the countries which they might chance to inhabit: and the ancient monks accordingly clad themselves in linen in Egypt, where it was a cheap and domestic manufacture; whereas the western monks used the habit common there, the pallium of the Greek philosophers, which many other Christians in those times did. The ancient tonsure, which was always practised on admission, consisted not in shaving the head, but in cutting the hair very short: their heads were wrapt in a cowl, in order that their attention might not be attracted and drawn aside by profane objects: their legs and feet were naked, except in very cold weather; and they generally made use of a long staff to assist their steps. The anchorites, however, were not so respectable in their appearance; they never bathed their limbs, or anointed them with oil; the bare ground, or at most a hard mat, was their bed; and the bundle of palm leaves on which they sat, during the day, served as their pillow at night. In course of time, the different orders of monks and friars were distinguished by their dress: the habit of the regular canons of Augustine was a long black cassock, with a white socket, and over that a black cloak and hood: they nourished their beards, and wore caps on their head: the habit of the regular canonesses was of the same colour as the habit of the canons. The habit of the Primonstrabensians was a white cassock, a socket over it, a long white cloak, and a cap of the same colour. The Benedictine monks wore a black loose coat or gown, made of stuff, reaching to the heels, a cowl of the same, and a scapulary—and under that another habit, as large as the former, made of white flannel, with boots on their legs. The Benedictine nuns had a black robe and scapulary, and under these a tunic of white or undyed wool; but during their attendance at the choir they wore a black cowl, similar to that of the monks. The Cistertian or Bernardine monks had the appellation of White Monks, from wear- a white cassock, with a narrow scapulary; when abroad they wore a black gown, but when attending the church, a white one: the nuns of the order wore habits of the same colour as those of the monks. The Dominicans, when abroad, wore a black cloak and hood over their white vestments, and in their convents they wore a white cloak and hood. The Francisans were called Greyfriars from the colour of their garment; their habit was a loose gown, reaching to the ancle, with a cowl and a cloak of the same; when they went abroad, they were barefooted, and girt themselves with cords. The dress of the Carmelite friars was a coat and scapulary of hair colour, with a white cloak and hood. The crossed or crutched friars anciently carried a cross fixed to a staff in their hand; but afterwards they substituted a cross of red cloth upon their back: their habit was of a blue colour. The Augustine friars wore a white garment and scapulary; but when in the choir or abroad, they wore a black cowl, with a large hood, and were girt with a black leather thong.

II. The rule of St. Benedict, founded on that of Pachomius, prescribed the original diet of the monks: according to it, they were allowed twelve ounces of bread, to be taken at two meals, one in the afternoon and one in the evening: the small loaves of six ounces each were called Paximaica. In some cases Pachomius allowed his monks a larger portion of bread, but they were obliged to work a longer period. The Egyptian monks were permitted to eat the small dried fish of the Nile: in process of time, different kinds of sea and river fish were allowed. Meat was expressly forbidden to be served to his disciples, except when illness absolutely required it: afterwards the flesh of birds, but not that of quadrupeds, was permitted: Cheese, fruit, sallad, were permitted; to abstain from boiled vegetables was deemed a merit. At the first institution of monachism, water was the only beverage. Benedict, because he could not persuade the monks to abstain altogether from wine, allowed them half a pint daily: this, in northern climates, where wine could not be easily and cheaply obtained, his disciples exchanged for beer or cider.

III. As at the institution of monachism, the monasteries had regular or permanent revenues, the monks were obliged to labour, in order to maintain themselves: but the produce of their labour went to the common stock; there was no private or exclusive property; such expressions as my book, my cloak, my shoes, according to Cassian, were not only forbidden, but severely punished. Their occupation consisted in cultivating the gardens and fields that belonged to the monasteries; in making their dress, utensils, and furniture; and sometimes, particularly latterly—as was particularly the case with the Benedictines, in cultivating science and classical literature. The Egyptian monks made wooden sandals, mats, and baskets, selling those which they did not need themselves. The monasteries, however, soon became rich, and then manual labour was neglected.

IV. The vows taken on becoming monks were those of poverty, obedience, and chastity; but originally these vows were not perpetually binding. Then the monastic life seems to have been a matter of free choice, not only at the monks' first entrance, but in their progress and continuance, and they might quit it without any punishment. The monks who married were not anciently obliged by law to dissolve their marriage: afterwards restraints were imposed in these respects. Whoever left his monastery was pursued and restored to it by the aid of the civil power. "The actions of a monk, his words, and even his thoughts, were determined by an inflexible rule, and a capricious superior: the slightest offences were corrected by disgrace or confinement, extraordinary fasts, or bloody flagellations; and disobedience, murmur, or delay, were ranked in the catalogue of the most heinous sins." The Egyptian monks, who seem to have been under the most rigid discipline, "were directed to remove an enormous rock; assiduously to water a barren staff that was planted in the ground, till, at the end of three years, it should vegetate and blossom like a tree; to walk into a fiery furnace; or to cast their infant into a deep pond." The spiritual exercises of the monks were perpetual repentance, extraordinary fasting, and extraordinary devotions. We have already mentioned, that originally the laws of monachism did not permit the monks either to wander about as mendicants, or to interest themselves in civil or ecclesiastical affairs; nor were they permitted to encroach on the duties or rights of the secular clergy, or to dwell in cities, but they were confined to the wilderness. "Whenever they were permitted to step beyond the precincts of the monastery, two jealous companions were the mutual guards and spies of each other's actions; and after their return they were condemned to forget, or at least to suppress, whatever they had seen or heard in the world. Strangers, who professed the orthodox faith, were hospitably entertained in a separate apartment; but their dangerous conversation was restricted to some chosen elders of approved discretion and fidelity. Except in their presence, the monastic slave might not receive the visits of his friends or kindred; and it was deemed highly meritorious, if he afflicted a tender sister or an aged parent by the obstinate refusal of a word or look."

V. Monasteries were commonly divided into several parts, and proper officers appointed over them: every ten monks were subject to one, who was called Decanus or Deacon: a centenarius presided over every 100. The principal monastic dignity was that of abbot: his power was very great; he was generally of a noble family, and his possessions as abbot were often very great. They were allowed to sit and vote in councils; originally their power was subordin te to that of the Bishop, and no one could build either an oratory or monastery without the consent of the Bishop of the district in which it was to be erected. The Dean used to keep an exact account of every man's daily task: this was brought to the steward of the house, who himself gave a monthly account to the abbot. The prior was often at the head of a great monastic foundation, but the abbey he ruled was generally subordinate to a greater abbey, from whence the officers and monks were brought; and the revenues were a part of the common stock. In some cases the subordinate abbey over which the prior presided paid an annual pension, as an acknowledgment of their subjection; in other respects, however, they acted as an independent body. The almoner had the oversight of the alms, which were duly distributed: The Pitancer distributed provisions on certain days above the common allowance. The chamberlain had the chief care of the dormitory. The cellarer was to procure provisions; the infirmarius took care of the sick; the sacrist of the holy vestments and utensils; the precentor or chanter directed the choir service.

The lands possessed by monasteries were held under the same tenure as all other land; and, till a comparatively late period, the abbots themselves led their quota of troops into the field. In the time of Charlemagne, fourteen monasteries of the empire furnished their proportion of soldiers. In 982 the bishop of Augsburg and the Abbot of Fulda were killed in the same battle. Charles Martel was opposed by troops collected and headed by an Abbot of Fontinelle.

Before concluding this article, we may add a few words respecting nuns. Their origin, institutions, rules, and presiding officers, were very similar to those of the monks. Originally there was a distinction between ecclesiastical and monastic virgins. The former were common in the church long before the latter. They were enrolled in the canon of the church; that is, in the catalogue of ecclesiastics. They lived privately in their father's houses, where they were maintained, or, in case of necessity, by the church. At first monastic virgins, or nuns, like monks, might mix again with the world, and even marry, without censure or punishment; but in the fourth and fifth centuries, the censures of the church began to be very severe against the marriage of perfect virgins. Before a woman was finally admitted to be a nun, it was necessary for her to pass her noviciate; after this, if she still persevered in her determination, she took the vows, and passed through the usual ceremonies; the principal of which were taking the veil, having their hair cut, and putting on a ring and a bracelet. The origin of the word nun is unknown; the right name is undoubtedly derived from the Greek *νοννς*, and the Latin *nonnæ*; but whence they are derived, or what is their original signification, has not been ascertained. Hospinian, in his treatise on monachism, says it is an Egyptian word, signifying a virgin; but Jerome applies it to widows preferring chastity, as well as virgins.

MONARCHY. See GOVERNMENT.

MONASTERY. See MONACHISM.

MONEY.

THE word Money is defined by Mr. David Hume to be, "the instrument which men have agreed upon to facilitate the exchange of one commodity for another."

In our articles BANK, BULLION, CURRENCY, and EXCHANGE, the subject of money has been considered under several points of view, and in our articles NUMISMATOLOGY and POLITICAL ECONOMY, we shall have occasion to view the subject under other aspects.

In the present article we propose merely to give an account of the moneys used by the different civilized nations of the globe.

General Table of Moneys of Account, containing the Value of the Moneys of Account of different Places (expressed in Pence and Decimals of Pence, according to the Mint Price both of Gold and Silver in England; that is, £3 17s. 10½d. per Oz. for Gold, and 5s. 2d. per Oz. for Silver. From Kelly's *Universal Cambist*, vol. ii. p. 169.

	Florin current	23 50	ditto

* In the places marked *variable*, the price of the coins is not fixed; and, therefore, the intrinsic value in gold of the moneys of account cannot be ascertained for any length of time.

† Where the columns are marked with a dash, it is to be understood that there is no coin in the metal of that column by which the moneys of account can be computed.

ALPHABETICAL TABLE

Of the State of the Real and Imaginary Moneys of the World.

† This mark is prefixed to the Imaginary Money, or Money of Account.

All Fractions in the *Value English* are parts of a Penny.

ABYSSINIA. See the article ABYSSINIA in vol. i. of this work.

ALEPPO, *Alexandretta*,

$3\frac{1}{3}$ Aspers	=	a Syaino.
24 Syainos	=	a Piastre.

ALTONA. See HAMBURG.

AMERICAN UNITED STATES.

		Value English. £	s.	d.
10 Mills	1 Cent	0	0	$0\frac{1}{2}$
10 Cents	1 Dime	0	0	$5\frac{7}{10}$
10 Dimes	1 Dollar	0	4	$3\frac{3}{4}$
10 Dollars	1 Eagle	2	3	$8\frac{2}{10}$

Almost all the coins of Europe are current in the United States; but the most common ones are Spanish dollars, and hence all other moneys have been referred to them.

Accounts are still kept in pounds, shillings, and pence currency, which varies greatly in the different States. The dollar in the currency of New York and Carolina is valued at 8s.; in New England and Virginia, 6s.; in South Carolina and Georgia, 4s. 8d.

ARABIA. *Medina, Mecca, Mocha, &c.*

A Carret		0	0	$0\frac{1}{8}$
$5\frac{1}{2}$ Carrets	a Caveer	0	0	$0\frac{125}{200}$
7 Carrets	a Comashee	0	0	$0\frac{2}{10}$
80 Carrets	a Larin	0	0	$10\frac{1}{8}$
18 Comashees	an Abyss	0	1	$4\frac{1}{5}$
60 Comashees	†a Piastre	0	4	6
80 Caveers	a Dollar	0	4	6
100 Comashees	a Sequin	0	7	6
80 Larins	†a Tomond	3	7	6

See the article ARABIA.

At Bassora accounts are kept thus—

10 Floose or Flouches	a Danim	0	0	$0\frac{5}{11}$
10 Danims	a Mamoodi	0	0	$5\frac{1}{2}$
100 Mamoodis	a Toman	2	5	10

The imaginary Toman and Mamoodi are only three-fourths of the value of the real ones.

At *Mocha* accounts are kept in Piastres of 80 Caveers current. Payments are made in Spanish Dollars, 100 of which pass for $121\frac{1}{2}$ Piastres; so that the Piastre is worth 3s. $8\frac{1}{2}$d. sterling.

AUSTRIA. *Vienna, Augsburg, &c.*

		Value English. £	s.	d.
A Fening		0	0	$0\frac{7}{60}$
2 Fenings	a Dreyer	0	0	$0\frac{7}{30}$
4 Fenings	a Cruitzer	0	0	$0\frac{7}{15}$
14 Fenings	a Grosh	0	0	$0\frac{19}{30}$
4 Cruitzers	a Batzen	0	0	$1\frac{13}{15}$
20 Cruitzers	a Kopfstuck	0	0	$8\frac{1}{4}$
15 Batzen	a Gould or Florin	0	2	4
90 Cruitzers	†a Rixdollar	0	3	6
30 Batzen	a Specie Dollar	0	4	8
60 Batzen	a Ducat	0	9	4

In a recent work, (*A Manual of Foreign Exchanges*, &c.) the Ducat is valued at 8s. 4d. and the rest in proportion.

BARBARY. *Algiers, Tunis, Tripoli, &c.*

An Asper		0	0	$0\frac{5}{9}$
3 Aspers	a Medin	0	0	$1\frac{2}{3}$
10 Aspers	a Rial old Plate	0	0	$6\frac{3}{4}$
2 Rials	a Double Real	0	1	$1\frac{1}{2}$
4 Doubles	a Dollar	0	4	6
24 Medins	a Silver Sequin	0	3	4
30 Medins	a Dollar	0	4	6
180 Aspers	a Zequin	0	8	10
15 Doubles	a Pistole	0	16	9

ALGIERS.

Accounts are now kept here in Saimes or Doubles of 50 Aspers, and in Patacas Chicas of 8 Temins or 232 Aspers.

3 Patacas Chicas	=	a Piastre.
$8\frac{1}{2}$ Patacas Chicas	=	a Sultanim.
2 Carûbes	=	a Temin.

A Pataca Chica is worth $11\frac{1}{2}$d. Sterling.

At *Tripoli* accounts are now kept in Piastres of 13 Grimellini, or 52 Aspers. The Piastre is worth 5s. 3d. Sterling.

At *Tunis* in Piastres of 52 Aspers; 12 Burbes being = 1 Asper.

BAVARIA. *Munich, Ratisbon, &c.*

White Money.

2 Hellars	1 Fennige	0	0	$0\frac{7}{80}$
4 Fennige	1 Kreutzer	0	0	$0\frac{7}{20}$
2 Kreutzers	1 Albus	0	0	$0\frac{7}{10}$

N. B. The decimal system of monies is in force in the Netherlands by the present laws; but for the convenience of trade several judicious regulations have been adopted. The silver coins are the *florin*, which is of the same intrinsic value as the ancient Dutch florin. This florin is subdivided decimally into *cents*, thus—

1 Florin	100 Cents
Piece of $\frac{1}{2}$ a Florin	50 do.
Ditto of $\frac{1}{4}$ a Florin	25 do.
Ditto of $\frac{1}{10}$ a Florin	10 do.
Ditto of $\frac{1}{20}$ a Florin	5 do.

The copper coins are *cents*, or 100dth parts of a florin, and *half cents*, or 200dth parts of a florin.

The gold coins are pieces of 10 florins.

In 1798, when the Helvetic Republic was formed, an uniform system of money was introduced at the different Cantons, viz. in Franken, Batzen, and Rappen, thus, 10 Batzen = 1 Franc ; 10 Rappen = 1 Batze ; the Franc was equivalent to $1\frac{1}{2}$ Franc of France.

TRIESTE.

Accounts are kept here in Florins of 60 Creutzers, each of the latter being subdivided into 4 Pfenings ; and likewise in Lire of 20 Soldi, a Soldo being = 12 Denari.

SPANISH ISLANDS.

Cuba, Trinidad, and Porto Rico. The moneys in these islands are the same as those of Mexico. In Trinidad, since the English possessed it, the moneys of the Leeward Islands have been adopted.

ZEALAND. See DENMARK.

ZANTE.

Accounts are kept in Reali of 10 Lire or 100 Soldi or Aspri.

For farther information respecting the moneys of different nations, the reader is referred to the following works. Zanetti, *Nuova Racolta delle Monnete, et Zecche d'Italia*, 5 vol. J. M. Benaven, *Le Caisscr Italien*, 1787, 2 vols., also the Works of Kruse of Hamburg, Ricard of Amsterdam, Marien of Spain, Gerhart of Berlin, Dubost of London. See also an useful little work, entitled *A Manual of Foreign Exchanges*, Glasgow, 1820, from which we have taken some of the preceding tablets; but particularly that elaborate and excellent work, Dr. Kelly's *Universal Cambist*, in 2 vols. quarto. Lond. 1811, which contains the most copious information on the subject of Moneys, Coins, Weights, and Measures.

MONK, GEORGE. See ENGLAND.

MONKS. See MONACHISM.

MONMOUTHSHIRE, a maritime county in the south-west of England, is bounded on the north-east by Herefordshire, from which it is separated by the river Mynnow; on the east by Gloucestershire, from which it is divided by the Wye; on the south-east by the æstuary of the Severn, which divides it from Gloucestershire and Somersetshire; on the north-west by Brecknockshire; and on the west by Glamorganshire, from which it is divided by the Rumney. Its length is about 33 miles; its breadth about 24; its circumference about 110 miles; and its area about 516 square miles, or 330,000 acres. In point of size, therefore, it approaches nearest to Herefordshire; and of all the counties in England surpasses only Rutlandshire and Huntingdonshire. It is divided into six hundreds—Skenfreth, Usk, Abergavenny, Wentlog, Caldicot, and Raglan. Its principal towns are situated on the banks of the Wye and the Usk, and are, Monmouth, the county town, at the confluence of the Wye and the Mynnow; Chepstow, near the mouth of the Wye; Usk, on the river of the same name; Abergavenny, also on this river; Pontypool, on the Avon, a branch of the Usk; Caerleon, at the confluence of the Avon and Usk; and Newport, near the mouth of the Usk. Monmouthshire returns three members to Parliament, viz. two for the county, and one for Newport, Monmouth and Usk, conjointly; and is in the province of Canterbury, and diocese of Lambeth.

The natural divisions of this county are strongly marked by the river Usk; the eastward and larger portion partakes of the character of the adjoining county of Hereford, and is well wooded, low-lying, and fertile; the smaller western part partakes of the character of Wales, being mountainous, and in great part unfavourable to cultivation, though there are several long, narrow valleys in it, watered by rivulets which flow into the æstuary of the Severn. "This is properly the county of landscapes. In other districts of our island, extent excites admiration, but in Monmouthshire all are home views; even where the æstuary of the Severn forms a part of the enchanting scene, the points of the horizon are the hills of Gloucester and Somerset. The course of the Wye is every where interesting, in some places sublime; that of the Usk, fringed with woods, or bounded by rich meadows, is a scene of perpetual beauty. The whole county forms but one exquisite landscape, of which the British channel is the foreground. Hills covered with woods, which the roads beautifully limit, or boldly climb; valleys fertilized by streams; thickets endlessly diversified; turrets rising in coverts, and ruined arches almost buried within them; mutilated castles, and mouldering abbeys, partially concealed; hamlets, churches, cottages, houses, and farms, are blended into one general and extensive scene, while the mountains of Glamorgan and Brecon melt into a distant and magnificent horizon." Such is a general picture of this county; and as it is interesting and important, chiefly from its beauties, we shall almost exclusively confine this article to those particulars which form or illustrate them.

The vale of the Usk is the largest tract of level ground in the inland parts of the county; it extends to the west of the town of Usk, along the lands watered by the Ebwy; and to the south, between the Usk and the elevated ground, almost to New-bridge; it is a rich and fertile district, but exposed to the overflowing of the Usk and Ebwy. There is another vale, called the Vale of Usk, which stretches from beyond Abergavenny along both sides of the river to the foot of Clytha hills. But the most romantic, as well as the least known of the valleys of Monmouthshire, are those which are called the valleys of the Ebwy and Sorwy. Under this description is included the mountainous district watered by the Rumney, and the streams that fall into it and the Usk, called the wilds of Monmouthshire. One of these streams bursts through a deep, narrow, and woody glen, and is discovered only by its foam glistening through the thick foliage; this rivulet is crossed by a stone bridge, which leads to a narrow and rugged path that winds round the sides of the Beacon mountain; these are thickly clothed with underwood, and most beautifully adorned with hanging groves of oak, alder, beech, and "the wild rasps twining in the thickets, and the ground covered with the wood-strawberry." The Valley of Ebwyfach, or, as it is called by the natives, the Valley of the Church, is now entered; it is bounded on the east by a ridge called Milfichill, which divides it from the parishes of Llanfoist and Trefrechin; and on the west by the Beacon mountain, which divides it from the Valley of Ebwyfawr. The Beacon mountain, a narrow and lofty ridge, stretches between the two branches of the Ebwy, and terminates very near their junction; the scenery at their junction is uncommonly striking; on the one side, the great Ebwy rushes through the vale; on the other, the little Ebwy, foaming through a hollow and narrow glen, emerges from a thick wood. On a bridge over the great Ebwy, whence a path leads up the woody side of the mountain which bounds the valley, "I remained," says Mr. Cox, "for a considerable time, absorbed in the contemplation of the picturesque objects around me; objects which recalled to my recollection the milder cast of mountain scenery, which I formerly so much admired in the Alps of Switzerland." The features of the vale of Sorwy are more wild and romantic than those of the Ebwy; it is deeper and narrower. There are several other valleys in this county, but those just described are the most picturesque and most worthy of description.

The mountains harmonize with the valleys, and give effect to the scene. They are seldom indented or notched, and never shapeless. The most remarkable are, the Skyrryd, or St. Michael's Mount, the Sugar Loaf, and the Blorenge. The ridge of the Skyrryd is about a mile in length, seldom more than 40 or 50 feet broad, and in some places only 10 or 12. Its insulated situation, abrupt declivity, and cragged fissures, produce a very striking effect, though its elevation is not very considerable. The highest part, according to General Roy, is 1498 feet. It is divided into two unequal parts, by a separation which, viewed from the west, seems an enormous chasm. The superstition of the county dates this rent at the crucifixion of our Saviour. Hence the natives generally call it the Holy Mountain. The chasm is not less than 300 feet in breadth. The view from this mountain is very extensive; in some parts rich and beautiful, in other points picturesque, and even sublime. The Sugar Loaf is higher than the Skyrryd, regular and beautiful, and its outline smooth and soft. The highest point rises 1852 feet above the mouth of the Gavenny. The ascent is so extremely easy, that a light carriage may be driven within 100 paces of the summit, which is an undulating ridge, about $\frac{1}{4}$ mile in length, and 200 yards in breadth. The view from it commands the counties of Radnor, Shropshire, Brecon, Monmouth, Glamorgan, Hereford, Worcester, Gloucester, Somerset, and Wilts, and of course comprises all varieties of scenery. The Blorenge mountain forms part of the chain which extends from the confines of Brecon to Panteg, below Pontypool. It forms the north-east boundary of the valley, called Avon Lwyd. It enters into the composition of some beautiful landscapes, but cannot bear a comparison with the Skyrryd or Sugar Loaf.

Another peculiarity of this county consists in its woodlands, forests, and chaces, some of which are still of great extent, though most of them have been diminished by grants. The forest of Wentword seems to have been one of the most considerable, and even yet comprises nearly 2170 acres, thickly covered with timber-trees and underwood. Besides the two grand natural divisions of this county formed by the Usk, there is a rich and extensive plain on the shore of the Severn, called Caldicot Level, or the Vale of Troggy, and the level of Wentlog. The former extends from the village of Caldicot, nearly the whole way to Goldcliff, and consists of a large tract of land recovered from the sea. Some parts of the walls, which have been erected at a very great expense, are 12 or 14 feet high, falling back from the sea by a gradual slope. The masonry is flanked by a strong embankment of earth. Near the western extremity rises a promontory, almost surrounded by the sea, called Goldcliff. It rises abruptly to the height of about 60 feet. In an extent of 16 miles, this rock is the only natural barrier against the encroachments of the sea. It consists of limestone lying horizontally, intersected with siliceous crystallizations above a large bed of mica. The level of Wentlog, like that of Caldicot, is perfectly flat, and defended from the encroachments of the sea by embankments. It stretches from east to west between the rivers Usk and Rumney; and from north to south between the Bristol Channel and a ridge of hills. The ground in both these levels is cut into parallel ditches: in some the water stagnates; in others it runs in streams, which fall into the sea through flood-gates. From this view of the surface of Monmouthshire, it appears that nearly one-third of it is a rock-plain on the shores of the Severn and Bristol Channel; one-third consists of ground, the surface of which is beautifully variegated, the hillocks being cultivated or woody, and numerous streams running through it; and "one-third assumes the mildest character of mountains, abounding with lovely valleys." The soil of the whole county is of various kinds, but generally rich and fertile, lying on limestone. The climate is mild and temperate, except on the highest mountains, where it is sometimes very cold. It has been remarked, that the fogs seem to shift periodically; for some days they rest on the mountains, while the valleys are free from them; and then suddenly the valleys are exposed to them for some days, and the tops of the mountains are clear.

The rivers contribute much to the picturesque beauties of this county. The principal are the Wye, Usk, and the Rumney. The tributary and inferior streams are the Mynnow, the Trothy, the Ebwy, the Avon, the Pill, and Kebby. The Wye is justly deemed the most picturesque river in England. It enters Monmouthshire near its junction with the Mynnow. The banks of the Wye at this place are rich with wood and verdure. A little below it is joined by the Trothy. Below Redbrook it forms a grand sweep, flowing into an abyss between two ranges of lofty hills, thickly covered with wood. Still lower down lies the singularly situated village of Llandogo, scattered among trees upon the side of a hill. Here the river forms a smooth bay; and the effect of the whole scene is greatly heightened by a beautiful back ground, formed of some undulating hills. A little below this the river again takes a meandering course, and the fine ruins of Tintern Abbey break upon the view. After passing some cliffs, marshy land disfigures the banks of this river; but these continue but for a short way, when the noble ruins of Chepstow Castle, placed on the highest point of an immense perpendicular rock, arrests the eye. Still further down the stream, the high impending screen of rocks on each side gives great effect to the scenery. This river is navigable to Hereford. At Chepstow, the tide sometimes rises to the height of 50 feet. The Usk rises in the mountains of Brecon, and enters Monmouthshire at Llangwnny. It is a clear stream, richly skirted with wood; the mountains, which stretch from Abergavenny to Pontypool, forming a magnificent back ground. Some parts of its banks do not suffer even when compared with those of the Wye, with respect to picturesque beauty. It is navigable for barges up to Tredannoc Bridge. The Mynnow rises in a lake at the foot of Mynnyd Maen, runs by Pontypool, passes under the canal, and joins the river Usk in the valley beneath. There are some lakes in this county, but none of them remarkable either for size or picturesque beauty. The largest is that from which the Mynnow takes its rise. It is two miles in circumference, and stretches along the foot of the north-east extremity of Mynnyd Maen. It forms the reservoir of the Monmouthshire canal.

There are two canals in this county. The Monmouthshire canal was begun in the year 1792, and cost about 280,000*l.* including the railways connected with it. It commences on the west side of Newport, forming a basin connected with the Usk. Its line lies between that town and the river, and it afterwards crosses the road leading to Chepstow; thence by Malpas it runs parallel to the Avon, and near it, close to Pontypool, to Pontnewidd. This is one line of the Monmouthshire canal. Its whole length is 11 miles, with a rise of 12 feet in the first mile, and 435 feet in the other 10 miles. The other branch strikes off near Malpas, parallel to the Ebwy, to the vicinity of Crumlin Bridge, having a course of nearly 11 miles from the junction, with a rise of 358 feet. The total length, therefore, of the two lines, is 22 miles, with 808 feet lockage. There are several rail-roads from each of these branches to the iron works, coaleries, lime-works, &c. which abound in this part of Monmouthshire. One of the rail-roads, which is nine miles long, cost 40,000*l.* The highest point of elevation of the principal rail-way is 1230 feet, making the whole elevation 2035 feet above the entrance lock. The Brecon canal unites with the Monmouthshire canal about 8 miles from Newport, and 1 from Pontypool. It crosses the river Avon, where it is carried through the high lands by a tunnel 220 yards long. It afterwards passes the town of Abergavenny towards the Usk, parallel to which it leaves the county. A canal has recently been formed, which, at the distance of about a mile from Abergavenny, communicates with the Brecon canal, and promises to open a considerable trade with the former town.

The western division of Monmouthshire is rich in mineral treasures, particularly iron and coal. Near the source of the Avon is Blenavon, where immense works are established, which usually employ upwards of 400 men. The iron is conveyed to the canal on the rail-ways. Between Abergavenny and Usk are the Trostey iron-works. Iron bar is manufactured here, and conveyed down the Usk to Newport. Iron is found in several other parts, chiefly in the vicinity of Abergavenny. There are also extensive iron-works at Abercorn, consisting of a foundery, wire mill, rolling mill, &c. The Monmouthshire canal passes through these works. There are also large iron works near Pontypool. There are indications of lead, but not any mines of consequence. Coal abounds; and, since the Monmouthshire canal was completed, a number of coaleries have been opened, which before were unknown or neglected. There are several large ones about 17 miles from Newport; one of which raises nearly 100 tons a day. They are generally worked by levels. There is no stone coal. As proofs of the great activity and increase which bas been given to the coal trade, by the formation of the canal, it may be mentioned that the coals exported coastwise from Newport average about 150,000 tons, principally to Bristol, Bridgewater, and Gloucester. To Bristol alone, about 40,000 tons are exported; whereas, before the canal was made, none were sent. There are many quarries of breccia for mill-stones, and other valuable stone for building. Lime-stone of the best quality abounds, especially in the eastern division of the county, where it is burnt on the spot for the general manure of the county. The rivers are well stocked with fish. The salmon of the Wye and Usk are much celebrated for their flavour.

The agriculture of Monmouthshire presents nothing interesting. The eastern division contains a good deal of arable land; and in some of the vales near the Rumney, a large quantity of corn is grown. There is also very fine pasture land in the eastern division. The western division is chiefly devoted to the feeding of sheep. This county is not remarkable for its native breed of cattle or horses; but the finest mules in the kingdom are reared and worked in it and Brecon. They are from 14 to 16 hands high, and sell for 30 or 40*l.* In the neighbourhood of Monmouth, oxen are much used in agriculture. Many of the peasants keep bees. Orchards, on a small scale, are not uncommon.

The iron works of this county have been already mentioned. There are also several other manufactures, principally of metal. Near Caerleon there are very extensive tin-works, which are capable of manufacturing annually from 14,000 to 20,000 boxes of tin plates, containing each from 200 to 300 plates. Iron plates are here rolled, and iron shop-bolts and square bars made. The machinery of the mill is entirely iron. The iron plates made here are used in the manufacture of the Pontypool japanned ware. This was the invention of Thomas Allgood, in the reign of Charles II.; it is still carried on, but has much declined since the rise in the trade of Birmingham. There is also a manufactory of japan ware at Usk. Not far distant from Tintern Abbey is a manufactory for making wire, which begins with the thick iron bar, and proceeds to the smallest wire.

The roads in Monmouthshire, which were formerly very bad, have been much improved of late years; and, though still unavoidably hilly, are in other respects as good as in most other parts of England. The following are the results of the last accounts respecting them laid before Parliament:

	Miles.	*Furl.*
Length of paved streets and turnpikes in 1814, - - - - -	264	7
——— all other turnpikes, - -	772	2
	1037	0

Estimated value of labour employed on them, - - - -	£4033	0	0
Composition money - - - -	712	0	0
Highway rates, - - - - -	5635	0	0
Law expenses - - - - -	284	0	0
Total,	£10,664	0	0

At the time of the Roman invasion, this county was comprehended in the Silurian territory. It was afterwards called Givent. It was never completely conquered during the Saxon dynasty. William I. however, in a great measure subdued it, by directing his barons to make incursions at their own expense, and granting them the lands they conquered, to hold under feudal tenure. These barons, however, afterwards entrenched in strong castles, bid defiance to their Sovereign; feuds and animosities also arose between them. At length Henry VIII. abolished their petty governments, and added Monmouthshire to the English counties. It was still, however, considered in law as a Welch county till the time of Charles II. It abounds in antiquities, or rather in ruins, highly picturesque in themselves, and rendered still more so by the scenery of the surrounding country. The most celebrated of these are Tintern Abbey, and the Castle of Chepstow. Piercefield, near Chepstow, the once celebrated seat of Valentine Morris, may also be noticed, as uniting, with wonderful taste and effect, all the softer and richer beauties of this most interesting country. Raglan Castle is another place worth noticing, on account of its ruins, and the valiant defence it made in favour of Charles I. under the Marquis of Worcester.

The following are the results of the last returns to Parliament, respecting the poor-rates of this county, for the year 1815:

Annual value of real property, -	£295,097	
Poor and other parochial rates, - -	38,650	
Rate in the £ - - - - -		2 6¾
Expended in maintenance of the poor, -	27,049	
——— in lawsuits and removals,	1,878	
Militia expenses, - - - -	583	
Church rates, &c. - - - - -	11,209	
Total expenditure, - - - - -	£40,719	
Poor supported out of workhouses, - -	2314	
——— in workhouses, - -	87	
——— occasionally - - -	1587	
Total,	4788	
Members of Friendly Societies, - -	8404	
Donations for Parish Schools, - -	£166	
——— for other purposes - -	783	
Total,	£949	
Poor, and other parochial rates in 1776, -	£7468	
——— average of 1783, 4, 5, - -	9989	
——— of 1803, - - - - -	25,048	
——— average of 1813, 14, 15, -	37,846	
Total relieved in 1803, - - - - -	3430	
——— average of 1813, 14, 15, - -	4122	
Members of Friendly Societies, in 1803, -	3799	
——— average of 1813, 14, 15, -	7923	

Number of persons relieved, on an average of 1813, 14, and 15, 6½ in each 100. The average rate levied on each individual, 12s. 2¼d. The average sum for support of each poor person annually, 6*l.* 16s. 5½d. 1-19th of the money raised expended on law; and 1-34th for militia purposes—¼th for all other purposes—total expended, independent of maintenance of the poor, is ⅓d.—13 in each 100, members of friendly societies.

In the hilly district enclosed by the Usk and the Rumney, which once formed a little principality, and which is said to have been left undisturbed by the Romans, Saxons, and Normans, the customs and manners of ancient Britain are preserved more pure than in any other part of Wales. The following are the results of the last returns to Parliament, respecting the population of this county.

Population in the year	1700 - - -	39,700
	1750 - - - -	40,600
	1801 - - -	47,100
	1811 - - - -	62,127

One baptism to 47 persons; one burial to 64 persons; and one marriage to 153 persons; the last is a very small proportion, the average of England being one marriage to 120 persons. The total number of baptisms, from 1801 to 1810, both inclusive, was 11,834; of burials 8832; and of marriages, 4058. The small number of burials and marriages, compared to the population, and the low proportion of baptisms to marriages, are very striking; particular inquiry was made, in consequence, into the parish register returns, but without discovering the cause.

Houses inhabited in 1811, -	11,766

MONMOUTH, the county town of Monmouthshire, in the hundred of Skenfreth, lies in an angle between the Wye and the Mynnow. It is a borough and corporate town, governed by a mayor, two bailiffs, and common councilmen. It returns one member to Parliament, in conjunction with the inhabitants of Newport and Usk. This privilege was conferred on it by Henry VIII. It is accommodated with four bridges; one across the Wye, on the road to Gloucester; two over the Mynnow, and one over the Trothy. The streets, which are in the form of the letter H, are in some parts broad and convenient, but in other places narrow and irregular. The castle, once a place of great strength, and celebrated for having been the birth-place of Henry V., who bore the name of Henry of Monmouth, is now almost entirely in ruins. It stood on the rise of an eminence, on the banks of the Mynnow. The east end of the church is much admired as a fine specimen of Gothic architecture. The county gaol, on Howard's plan, combines strength, utility, and comfort. The walks in the vicinity are very pleasant; though these and the town itself are frequently enveloped in exhalations, occasioned probably from its low situation, and the vicinity of the rivers. Monmouth carries on a considerable trade with Bristol, by means of the Wye. It has three fairs, at which a large number of cattle, horses, sheep, and pigs, are sold; and also a large quantity of flannel. Its market is well supplied with all sorts of provisions. In 1801, it contained 667 houses, and 3345 inhabitants. In 1811, its population was as follows:

Houses inhabited, - - -	661

MONOCHORD, from *μονος*, *single*, and *χορδα*, *chord*, signifies properly any musical instrument which has only *one chord* or string, but is applied also to an instrument said to have been invented by Pythagoras for measuring geometrically the quantities and proportions of sounds. A paper by Dr. Wallis, on the division of the monochord, will be found in the *Philosophical Transactions* for 1698, vol. xx. p. 80.

MONONGAHELA, a river of the United States of North America, rises in Randolph county, Virginia, interlocking with the sources of the Great Kenhawa at N. Lat. 38° 30′. Its course is nearly south 80 miles, to where it receives the west branch, from Lewis and Harrison counties. Below their junction, the united stream flows south-east 30 miles to the south boundary of Pennsylvania, which it passes, and two miles lower receives from the south-east, Cheat river, little, if any, inferior in column or length to the Monongahela itself. Cheat river rises in Randolph county, and flows through that and Monongahela county, enters Pennsylvania, and unites with the main stream as before noticed. The sources of the Monongahela and Cheat are in the western spurs of the Appalachian mountains. Below the mouth of Cheat, the Monongahela flows nearly south 50 miles, to its junction with the Youghiogheny. The latter rises in the Appalachian mountains, in Allegheny county, in Maryland, interlocking with the sources of the North Branch of the Potomac, flows north into Pennsylvania, passing through Fayette, Westmoreland, and entering Allegheny county, unites with the Monongahela at M'Keesport, after a comparative course of about 100 miles. Twelve miles below its junction with Youghiogheny, the Monongahela unites with the Allegheny, and forms the Ohio at the city of Pittsburg. The entire length of the Monongahela river, by comparative courses, is about 170 miles, but following the meanders of the streams, either along the main or Cheat branch, the length exceeds 200 miles.

The country drained by the Monongahela is in some parts mountainous, and in all hilly.

For down stream navigation, the Monongahela, at high water, is passable with large boats as high as the mouth of the West Branch, and by lighter vessels much higher. Cheat river is navigable into Randolph county, about 50 miles comparative course above its mouth, and the Youghiogheny to the Ohiopyle falls, in Fayette county, 60 miles above its junction with the Monongahela. (Darby.)

MONRO, M. D. ALEXANDER, the son of Mr. John Monro, was born at London on the 19th September 1697, and descended, by his father, from the family of Monro of Milton, and by his mother from that of Forbes of Culloden. John Monro, the younger son of Sir Alexander Munro of Bearcroft, colonel in the army of King Charles at the battle of Worcester, and afterwards one of the principal clerks of the Court of Session, served for some years as a military surgeon under King William, in Flanders. Retiring from the army about the commencement of the last century, he established himself at Edinburgh, where his enlarged knowledge, unremitting attention, and agreeable manners, soon introduced him to an extensive practice. At the same time, professional engagements did not prevent him from attending to the education of an only son, whose early inclination to the study of medicine contributed to strengthen the desire he had long felt to supply the want of medical instruction in Edinburgh.

Mr. Monro, after receiving an excellent classical and mathematical education, and completing the usual course of academical studies, was bound an apprentice to his father, who procured him books necessary for his private studies, and a chemical apparatus for the purpose of repeating at home the experiments performed by Dr. Crawford, in illustration of his lectures on chemistry. He was entrusted with the sick pensioners under the charge of his parent, and permitted by the rest of the physicians and surgeons to attend many of their patients, who were affected with rare and dangerous diseases. He accurately examined the pharmaceutical plants, exhibited by Mr. George Preston; and availed himself of the means afforded by Messrs. Elliot, Drummond and M'Gill, the professors of anatomy, for observing the few occasional dissections which occurred in Edinburgh. The medical world, therefore, is much indebted for the valuable fruits produced by the subsequent labours of Mr. Monro, to the care with which the germs of his youthful mind were nurtured and developed by the combined assistance of his excellent father and the other distinguished practitioners in Edinburgh.

After completing the regular term of his apprenticeship, together with the usual studies in Edinburgh, he went to London in the year 1717, for the purpose of attending the lectures on experimental philosophy by Professors Hawksbee and Whiston, and the anatomical demonstrations by the illustrious Cheselden. It appears from the second edition of Mr. Cheselden's works, in 1726, that in consequence of Mr. Monro's communications, he had altered and improved almost *every part* of his anatomy. In London he was supplied with great opportunities for dissection, in which he acquired a dexterity and accuracy that laid the foundation of his future celebrity as an anatomist. The pupils of Cheselden were encouraged, by being allowed the use of his theatre, to form a society for mutual instruction, where they alternately gave lectures concerning the structure and uses of the different organs of the body; on which occasions young Monro frequently acted as demonstrator to his fellow-students. The ardour with which he pursued dissection in London endangered his life, by an attack arising from inoculation with morbid matter. He was also very industrious in forming anatomical preparations, which he sent to his father, by whom they were deposited in the museum of curiosities at Surgeons' Hall; and their great excellence induced Mr. Adam Drummond to promise his father, that if the future attainments of his son corresponded with such early exertions, he would, on the completion of his studies, resign the anatomical chair in his favour.

In 1718, he attended the hospitals in Paris, and the lectures of Chomel on botany and chemistry, of Gregoire on midwifery, Cessau on bandages, and those of Bouquet on anatomy. He performed, under the superintendance of M. Thibaut, the different operations of surgery, and was particularly attentive to morbid dissections.

In the autumn of the same year he repaired to Leyden, and became a pupil of the illustrious Boerhaave, who, having himself, twenty-six years before, derived much instruction and assistance in medical inquiries from Dr. Pitcairn, was enabled to return it with interest to this future ornament of Scotland, and distinguished improver of anatomical and surgical science. He carefully attended the lectures of Professor Boerhaave on chemistry, on the theory and practice of medicine, as well as his clinical lectures in the hospital. The study of comparative anatomy was also cultivated by him, and he pointed out its advantages to some of his fellow students.

The frequent opportunities afforded our young student of conversing with this eminent physician, in consequence of consulting him on important and novel cases from Scotland, convinced Dr. Boerhaave of the superior attainments and abilities of his pupil. His persevering application and study were clearly proved by the numerous MS. notes of lectures which he wrote.

This account of the labours by which the active mind of so great a benefactor of his country was enabled to stamp its own character on the rising generation of anatomists and physicians, must convince the most inconsiderate that no lasting attainments can be secured, without enlightened instruction, close application, and patient investigation.

His own observations and experience fully convinced him that dissection is the only method by which a correct system of the different branches of medical and surgical knowledge can be formed or improved. He also endeavoured, by maintaining and nourishing his favourite science from the common stock of natural philosophy, to promote its growth and vigour. Empiricism was thus prevented from continuing to maintain its influence, and truth enabled to acquire that ascendancy which it is entitled to claim.

Impressed with such views, young Monro, for he was then only twenty-two years of age, returned to Edinburgh in 1719, and succeeded, the following year, to the anatomical chair, on the resignation of Messrs. Drummond and M'Gill, at that time professors and demonstrators to the College of Surgeons, who thus testified the high opinion which they entertained of his qualifications, and fulfilled the promise made to his father. Soon after his appointment, he was induced to deliver a course of lectures on anatomy, and to illustrate them by his own preparations, made under the tuition of Cheselden and others.

The following fact affords a striking proof of his great abilities and self-possession as a public speaker. The unexpected presence of a large and respectable assembly, among whom were the Presidents and Fellows of the College of Physicians and Surgeons, who attended the first lecture, at the request of his father, not only disconcerted the professor, but deprived him of the recollection of what he had committed to memory. With a view to recal his scattered thoughts, he began to show some of his anatomical preparations, and determined at last to adopt such language as an intimate and extensive acquaintance with the subject might suggest. His great success on this occasion induced him to adhere, during the long course of forty years, to the same plan, and few lecturers ever surpassed him in ease, elegance and perspicuity of language.

Provost Drummond, a magistrate of a truly liberal and comprehensive mind, afforded young Monro every assistance, by means of his influence with the Town Council, and sanctioned the plan of teaching which he had adopted, by frequent attendance on his lectures.

The anatomical school of Edinburgh, established on such a firm foundation, and conducted by so able a professor, soon rivalled the university of Leyden itself, which had acquired the greatest celebrity from the exertions of the distinguished Boerhaave. Mr. Monro added much to the riches of Edinburgh, since his lectures were attended by 3850 students, who must have spent, on the most moderate calculation, the sum of £192,500. This fact affords the strongest proof of the uncommon success of his lectures, which were conducted in the following manner. After giving a view of the history of the science, examining the structure of the bones and the different parts of the body in a state of health, as well as the analogous organs of the inferior animals, he illustrated the whole by reasonings, calculated to point out the nature and character of the healthy functions, which he applied to the elucidation of disease and the improvement of surgery.

A hospital was still wanting, where the intimate connection between anatomy, surgery and medicine might be shown, and his father used every exertion to complete a plan on which the prosperity of the rising school depended. Mr. Monro himself also wrote a pamphlet, pointing out its advantages. The sum of 2000*l.* was, after some time, collected, and a temporary hospital erected in 1729, which was superseded by the present one, whose foundation was laid in 1738. Some of the principal rooms, particularly that for operations, were constructed according to a plan of the professor. By the mutual co-operation of all classes of citizens, this useful building, which is capable of holding nearly 300 patients, and open for the reception of the sick of all nations, was completed in a shorter time than could have been expected.

Provost Drummond was appointed by the first contributors to superintend, in conjunction with Mr. Monro, the erection of the hospital. In this spacious building the pupils of our professor learned to adopt humane and feeling manners towards their patients, while they were instructed in the best mode of curing diseases. He never absented himself from any dissection; and in all instances of death, whether from accident or disease, he not only pointed out to the students the difference between the healthy and morbid appearance of the various organs, but carefully explained the practice which had been adopted. The intimate acquaintance which he possessed of anatomy, and his knowledge of a vast variety of cases, enabled him to perform surgical operations with success, and gave him great superiority as a consulting physician and surgeon. He manifested his deep sense of the utility of clinical lectures, by continuing them with unwearied industry, after that disease had begun which terminated his useful career.

Mr. Monro assisted in establishing a society of physicians and surgeons, and six volumes of medical essays and observations were published by him as secretary, which he considered to be the best means of increasing the knowledge of medicine; and when, at the recommendation of Colin Maclaurin, the society was enlarged by the admission of philosophers as members, he contributed several valuable papers to the two volumes which were published during his life by the Philosophical Society, under the title of Physical and Literary Essays.

His conduct to Dr. Martin, private lecturer on anatomy at Edinburgh, exhibits a liberality of sentiment deserving of imitation, since he acted towards him with the greatest kindness while living, and undertook to superintend the publication of his works on anatomy after his death.

Dr. Monro has rarely been surpassed as a man of business, and he obtained great influence over his fellow citizens by his extemporaneous eloquence. He was a director of the Bank of Scotland, a justice of the peace, a commissioner of the high roads, and a manager of many public charities, and fulfilled the various duties which such situations require with great regularity and honour.

He was a steady supporter of civil liberty,—firmly attached to the House of Hanover, and manifested great attention and humanity to the wounded officers and soldiers who fell at Prestonpans. He evinced great compassion and benevolence to the rebels, not only by procuring pardon for them, but by cheerfully affording professional aid, which was of great use to those who had suffered in the army of the Pretender. His friendship with Colin Maclaurin, the friend and commentator of Newton, who was appointed professor in the year 1725, when Dr. Monro delivered his first lecture in the University, affords a strong testimony of the esteem and affection in which he was held by his intimate acquaintance.

Mr. Monro's influence as a teacher was much increased by the exterior graces of a well-formed person and gentle manners, which were combined with an amiable disposition, and the ennobling dignity of a comprehensive and liberal mind. It was his great object to perform professional duties with a spirit of true philanthropy, endeavouring to make his own experience subservient to the knowledge of others, as well as to the advancement of the healing art. He endeared his patients by an affectionate conduct, and his charitable attention to the wants and diseases of the poor secured their regard and esteem.

He performed the duties of a son, a husband, and a father in the most exemplary manner. His father, to whom Edinburgh is much indebted for her prosperity, died in Berwickshire, at the seat of his only son, whose success as a professor had contributed to gladden his declining years. He was very attentive to the education of his sons, instructed them in many of the sciences himself, and treated them through life with all the familiarity of a friend.

Dr. Monro frequently laboured under a spitting of blood when he caught the least cold, and was subject to inflammatory fevers. After an attack of the influenza in the year 1762, he was severely afflicted with a fungous ulcer of the bladder and rectum, which he bore with great patience and Christian resignation, and died with uncommon composure on the 10th of July 1767, at the age of seventy.

The works of Dr. Monro were published after his death by his son Alexander, professor of anatomy, in one 4to volume. The luminous order, and accurate philosophical description which characterize his writings, have secured him the admiration of all succeeding anatomists. His Osteology, the outlines of which were first read to a medical society, when he was student in London, is yet unrivalled. The methodical and simple arrangement that he has adopted in this work, must continue to be a model for every interpreter of nature, who wishes to follow her direction and not his own imagination. After showing the situation, general appearances, and divisions of the bones, he points out the connection of the one he examines with those around it, and concludes by enumerating the purposes which the bone serves in the animal economy, and stating its diseases. The Introductory Letter to the first edition of his Comparative Anatomy, is an able defence of this important branch of science. His Comparative Anatomy is excellent; and nothing affords so striking a proof of the range of Monro's mind, and the correctness of his reasoning, as the intimate union he assisted in establishing between comparative and human anatomy, from which he endeavoured to deduce his physiological observations. It clearly appears from his papers on medicine and surgery, that he was amongst the first, who, by conducting manual operations according to the light of science, assisted to rescue surgery from barbarism and ignorance, and to restore it to that rank and estimation which so useful a part of the medical profession is fully entitled to claim. His last work on inoculation in Scotland, written at the age of sixty-eight, evinces with what eagerness he continued to promote improvements in medicine, and to check the progress of prejudices injurious to the health, the comfort, and the lives of his fellow-men.

See *Life of Dr. Monro*, Primus, *prefixed to his Works*; Dr. Duncan's *Account of his Life*; Bowers' *History of the University of Edinburgh*, vol. ii. p. 166—188; Dr. Barclay's *Preface to a Series of Engravings, representing the Bones, by* Edward Mitchel, Engraver, Edinburgh; and *The Medical School of Edinburgh.*

ALEXANDER MONRO, *Secundus*, M. D. the youngest of the three sons of Dr. Alexander Monro, *Primus*, and Isabella M'Donald, second daughter of Sir Donald M'Donald of M'Donald, in the Isle of Sky, Baronet, was born at Edinburgh on the 20th of March 1733. He acquired the first rudiments of classical literature under Mr. Mundell, a distinguished teacher in Edinburgh, whose kindness and exertions were long remembered by his grateful scholars. His father, from a deep conviction that an intimate acquaintance with the principles of mathematical, physical and ethical knowledge, is the best preparation for medical enquiries, placed him under the tuition of his bosom friend, Colin Maclaurin, the Professor of Mathematics, Dr. Stewart, and Sir John Pringle. He did not commence the study of medicine under his father before he had attained his eighteenth year, when an enthusiastic diligence and ardour soon made him a useful assistant in the dissecting room. It was here, like Cheselden, Haller, and Albinus, that he obtained an accurate acquaintance with the structure and functions of the human body by constant dissection, the only sure basis on which medical and surgical improvements can be founded.

He studied the various branches of medicine under Professors Rutherford, Sinclair, and Alston, and prosecuted his labours with such unremitting perseverance, that in the year 1753, at the age of twenty, he assisted his father in his anatomical lectures.* He graduated in 1755, when his inaugural dissertation, *De Testibus et Semine in variis Animalibus*, displayed a minute knowledge of the physiology of these organs, and of the lymphatic system, which he afterwards investigated with so much success. His superiority as a demonstrator and lecturer induced the patrons of the University, in consequence of a petition from the father, to appoint him Professor of Anatomy and Surgery, on the 12th July 1755, and in the twenty-second year of his age.

Dr. Monro, *Primus*, manifested great solicitude in

* Dr. Monro, *Primus*, graduated after his son.

procuring testimonials, not only from the different professors, but also from such students as attended the demonstrations of young Monro, with a view to satisfy the patrons, in the most effectual manner, of his son's diligence and talents.

When Dr. Monro, applied, on this occasion, to the Town Council, and presented the testimonials of his son's character and abilities, Mr. Stuart, son-in-law of the former professor of anatomy, Mr. Drummond, and senior magistrate during the absence of Provost Drummond, at that time in London, told him, "he had no need or wish to inspect them. Tell me," said Mr. Stuart, "your own sentiments of him; for I am sure every one will trust you rather than any other person." "As you refer to me, then," observed the Professor, "you may believe me when I say, that if the world gives me credit for any ability or effect in promoting the character and usefulness of the University, I think more highly of him than they can think of me." He seems also to have been induced, by an anxiety for the prosperity of the College, to select as a professor the younger son in preference to the elder, from a conviction that the natural and acquired attainments of the former were better calculated to maintain the honour of the University than those of the latter.

Dr. Monro, *Primus*, being yet in the vigour of life, and an enthusiastic teacher of anatomy, sent his son to prosecute his studies under the most eminent professors at London, Paris, Berlin, and Leyden. Whilst the pupil of the celebrated Professor Meckel at Berlin, he resided in his family, and thus enjoyed all the advantages of public and private instruction. In 1758, Dr. Monro published at the same place his *Essay de Venis Lymphaticis Valvulosis*, for the purpose of proving, more at large than in his Thesis, that the valvular lymphatics are one general system of absorbents. The first preparation of the Acoustic Nerve, and the most minute ramifications of the lacteals, were made by him during his residence with Dr. Meckel.

He remained only a short time at Leyden, as Albinus, whose lectures he wished to attend, was confined with disease. This university, only 20 years before, had been justly considered the luminary of the medical world, but its splendour was eclipsed by the removal of the celebrated Albinus, Professor of Anatomy, and by the neglect of the patrons of the university to secure lecturers of distinguished ardour and intelligence. The genius and fame of Meckel had raised Berlin to the honourable rank which Leyden so recently possessed, and brought students from every quarter of the globe, to enrich that capital with science and wealth.

Dr. Monro returned to Edinburgh in the summer of 1758, where he was admitted a licentiate of the Edinburgh Royal College of Physicians on the 2d May, and elected a fellow on the 1st May, 1759. He also succeeded his father as secretary to the Philosophical Society. In the autumn of 1758, he commenced his lectures as colleague with his father, and combined in his own person the knowledge of some of the most celebrated anatomical professors of the last century, Cheselden, Boerhaave, Monro and Meckel. We need not be surprised to find the fame of the University of Edinburgh constantly increasing under a lecturer enriched with the treasures of such eminent anatomists, directed by the constant instruction and superintendance of his own parent, and whose ardent enthusiasm was regulated by the dictates of a comprehensive judgment and acute discrimination. His course of anatomical lectures was arranged nearly according to the same connected and orderly plan with that of Monro, *primus*, who continued to witness, during the space of nine years, the uncommon success of his son in the advancement of that instruction which he had begun. The demonstrations of our professor were conducted with a simplicity, accuracy and distinctness, which never failed to instruct and delight his students, and few men surpassed him in exciting a taste for that branch of science which he so ably communicated. The number of pupils who attended his lectures was 14,000, averaging nearly 350 annually. If, with Dr. Monro, *primus*, we calculate the expense of each student at 50*l.* per annum, the riches introduced into Edinburgh by the lectures of his son would amount to 700,000*l.*; and these two distinguished individuals may be considered as having added 892,500*l.* to the improvement of Edinburgh and its inhabitants.

A controversy was maintained with great warmth, betwixt Dr. William Hunter of London and Dr. Monro, on the subject of their respective claims to the discovery of the use of the lymphatics, which contributed to make both examine this part of anatomy with greater minuteness; and to their rivalship we are indebted for the intimate knowledge of that beautiful system of vessels, by which their office as absorbents is established with a certainty and clearness that remove all doubt.

The following statement by Dr. William Hunter, in his treatise on Aneurism, in the 6th volume of *The London Medical Observations and Enquiries*, affords a striking proof that he did not suppose the solid parts of the body were taken up by the lymphatic vessels.—"In this case (Aneurism) the appearance was rather as if the blood had insensibly *dissolved and washed away the substance of the bone*, as we see in stones of unequal texture, that have been long washed by a dropping, or a stream of water."—See Dr. Winterbottom's Thesis, *De Vasis Absorbentibus*, 1781, who gives a full account of Dr. Monro's opinion respecting the absorption of solids.

Dr. Monro's lectures are universally acknowledged to have been the fullest course of anatomy, physiology, pathology and surgery ever delivered. Dr. William Hunter was surpassed by none as a demonstrator or lecturer, but he paid too little attention to physiology, and on this account Dr. Monro, who for 40 years performed the arduous duties of the anatomical chair without an assistant, is entitled to greater praise than his powerful rival. He delivered his lectures until the year 1800, when his son, the present Professor of Anatomy, who had been conjoined with him in 1798, began to assist him. He continued, however, his surgical course until the year 1807, and delivered the introductory lecture for the session 1808-9, when he was 76 years old.

By a happy union of anatomical and medical knowledge, Dr. Monro was distinguished as a consulting surgeon, and displayed uncommon acuteness, correctness, and humanity in the direction of operations; and in surgery, to make use of the words of a very competent judge, Mr. B. Bell, "his improvements were numerous and important."

Dr. Monro commenced the practice of a physician on his return from the continent; and his skill and success have seldom been equalled by any practitioner in this city. For the attainment of so high an honour, he was indebted, in no small degree, to the habit of keeping a regular account of every case which came under his care, with the addition of such notes and observations as his good sense and accurate judgment supplied. His great object was to have recourse to simple and powerful remedies, whose efficacy was sanctioned by just reasoning, or extensive experience. With a mind uninfluenced by the dogmas of particular sects or parties, he was always prepared to adopt such new modes of practice as his increasing knowledge approved; and to accommodate his prescriptions to the various changes of diseases, which habits of accurate observation enabled him to discern. Few practitioners were more alive to the condition of a patient than our distinguished physician, who investigated their complaints with a caution and feeling that showed deep interest in the afflictions of the sufferer. This conduct inspired a confidence in his attentive kindness, which frequently promoted the recovery of those entrusted to his care.

As a consulting physician, Dr. Monro merited the highest praise. He entered into no subtle disquisitions or controversies about difficult or disputed points; he showed no credulity as to the virtues of particular remedies, nor did he arrogate to himself any superior skill, by boasting of his own success, but was always prepared to propose or adopt such active remedies as promised to be of essential benefit in difficult cases.

The celebrity of our Professor extended his fame throughout Europe, and he was admitted a member of the royal academies of Paris, Madrid, Berlin, Moscow, &c.

His favourite amusement was horticulture, which he pursued with much pleasure during the greatest part of his life.

Our Professor, in the midst of his other numerous labours, did not neglect to attend to his duties as secretary of the Philosophical Society, whose essays he continued to publish during the flourishing period when Lord Kames was president, and Sir George Clerk, Mr. John Clerk, Drs. Cullen, Home, Hope, Black, Young, Duncan, Hutton, &c. were members. An excellent paper of his, concerning the effects produced by narcotics and stimulants on the nervous system, in the 3d and last volume of this work, throws considerable light on the use of this important part of the animal economy. The same volume also contains some valuable remarks on polypous tumours in the pharynx and œsophagus, and on the use of mercury in convulsive diseases. In consequence of the proposal of Principal Robertson and Professor Dalzell, the Philosophical Society was incorporated by charter, in the year 1782, into the Royal Society of Edinburgh, and Dr. Monro resigned the office of secretary: he still, however, continued an active and useful member, and enriched their transactions with some excellent communications on animal electricity and galvanism, and on the effects of the oblique insertion of muscular fibres.

Dr. Monro was not so tall as his father, but had the same amiable mildness of countenance, and manifested the same benevolent pleasure in promoting the happiness, or alleviating the wants and distresses of his fellow-men.

He pursued the study of polite literature with his usual ardour, and introduced into his lectures, in a very appropriate and judicious manner, the stores he had acquired. He neglected no opportunity of extending his acquaintance with every department of knowledge, as far as these studies did not interfere with his professional, civil, or social duties. His character as a husband, father, friend, and landlord, was distinguished for affection, tenderness, kindness, and generosity. In his temper he was cheerful and candid, lively in conversation, pleasing in his manners, and conciliating in his disposition.

At last, after devoting more than 60 years to the service of mankind, he was attacked by a slow and painful disease, which terminated an active and valuable life, in the 85th year of his age. Under long confinement, increasing feebleness, and the prospect of greater affliction, his patience and resignation were most exemplary, and together with great thankfulness for past blessings, he displayed a humble confidence in the mercy of Him by whom his sufferings were inflicted.

In 1783, Dr. Monro published observations on the structure and functions of the nervous system, and has traced, farther than any of his predecessors, the olfactory nerve, the nasal twig of the ophthalmic branch of the 5th pair, and the vidian branch of the superior maxillary nerve. By ascertaining that these nerves are distributed on the same membrane, he contributed to the discovery of the sense of smell residing in more nerves than former anatomists acknowledged. He has also extended our acquaintance with the smaller branches of the auditory nerve and the nerves of the teeth.

In 1785, he published an excellent work on the structure and physiology of fishes, showing that the absorbent functions of the lymphatic system exist equally in birds, fishes, and amphibious animals, as in men and quadrupeds. He has demonstrated, in his Treatise on the Brain, the existence of lymphatics in that organ, by filling them with a coloured injection. His pathological and surgical observations in this work are extremely valuable, and point out the communication between the lateral ventricles of the brain, the seat of the water in Hydrencephalus; and that the changes in the texture of the brain are proved to be the result of absorption. In his Treatise on the Eye, he has described the muscular structure of the iris, the nature and course of the retina, concerning which Morgagni, Winslow, Haller, and his father, held different opinions, and has endeavoured to establish, by experiments, that the oblique muscles of the eye-ball, and the orbicular muscle of the eye-lids, are the means by which the eye is adapted to objects at different distances. In his Treatise on the Ear, he has published the most full and accurate description of the human cochlea,—of the smaller branches of nerves distributed upon its several component parts, and supplied many new facts respecting the ear of the whale, skate, tortoise and angel fish. In 1788, he published a work on the Bursæ Mucosæ, which adds to his character as a good anatomist and profound pathologist.

Such were the lives of the two Monros, who contributed to extend the boundaries of medical science, by promoting the advancement of valuable discovery and improvement—to divide at first the honour of medical degrees between Leyden and Edinburgh,—and finally, to raise the metropolis of Scotland to the highest celebrity as a school of medicine.

See *An Account of the Life, Writings, and Character of the late Dr. Alexander Monro*, secundus, by Dr. Duncan, senior.

MONS, (MONTES HANNONIÆ,) a town in the kingdom of the Netherlands, and the chief place of the province of Hainault, is situated partly, on a hill, upon the river Trouide, which traverses it. The town is well built, and contains several good squares and streets. The principal public buildings and institutions are the Hotel de Ville, a large old building, with a fine steeple, erected in 1716, and situated in a square; the Government house, situated in a spacious market-place; the Chateau and its gardens; the ci-devant Abbey of Wantru; a large hospital, originally constructed by Vauban; a commodious foundling hospital; a gymnasium, with a good library. The churches are well built. The great church is a fine building, the side altar and chapel being formed of pure marble. That of St. Elizabeth occupies the site of an ancient castle, demolished in 1618, and said to have been erected by Julius Cæsar. The town is surrounded by an earthen mound and ditches; and, since 1818, its fortifications have been increased. The manufactures of Mons are woollen, cotton, linen, and lace. It possesses also iron founderies, and works for salt, pottery, oil, and soap, which, from its command of coal, and its communication with Paris by the canal of St. Quintin, it carries on to great advantage. Population 20,000. East Long. 3° 57′ 15″; and North Lat. 50° 27′ 2″.

MONTAIGNE, (Michel de) a celebrated French writer, was born at the Chateau de Montaigne, near Bergerac, upon the Dordogne, on the 28th of February, 1533. He was the third son of Pierre Eyquem, a man of rank and probity, who appears to have discharged the paternal duties with extraordinary care. Young Michel was awakened every morning by soft music, lest sudden excitation might injure his health; and a German domestic, unacquainted with the French language, taught him to express his first ideas in Latin. At the age of six years, he was sent to the College of Bordeaux, then conducted by the most celebrated preceptors in France, one of whom was our distinguished countryman, George Buchanan. Montaigne's knowledge of Latin, acquired in a manner so uncommon, was here of some avail to him; and though we may be allowed to doubt his assertion, that the masters 'were afraid to accost him,' the instructions of his nurse must have materially contributed to form that minute and extensive acquaintance with classical literature, and that strong tinge of Latinity, for which his writings are so remarkable.

After seven years occupied in such studies, Montaigne, with the view of becoming a lawyer, engaged in the requisite course of preparation; but his love of jurisprudence, and his progress in that science, appear to have been equally small. The Parliament of Bourdeaux seldom witnessed his official exertions; and after his elder brother's death, from the stroke of a tennis-ball, he gladly exchanged the advocate's gown for the sword of a country gentleman. A short time after, 1560, he married Françoise, daughter of a celebrated pleader, Joseph de la Chassagne; and, possessing the Chateau de Montaigne, which his father bequeathed to him in 1569, enjoying a competent fortune and domestic happiness, he had full leisure to combine rural and intellectual employment in the most suitable proportion. Study seems, however, to have attracted nearly all his attention; riding afforded a healthful and favourite exercise; he lived remote from the political quarrels which, at that period, distracted his country; and few avocations enticed him from reading, or committing to paper such reflections as that reading excited, in whatever order they occurred. Before the decease of his father, Montaigne had translated the Natural Theology of Raymond de Sebonde; and, in 1571, he superintended the posthumous publication of his friend, the Sieur de la Boëtie's works. He did not appear in the character of an original author till 1580, when the fruit of his meditations was published under the title of Essays, at Bourdeaux. Eight years afterwards, in a new edition prepared under his eye at Paris, the work was augmented by a third book, and many additions to the part already published.

In this singular production, Montaigne completely fulfils the promise of 'painting himself in his natural and simple mood, without study or artifice.' And though Scaliger might perhaps reasonably ask, "What matters it whether Montaigne liked white wine or claret?"—a modern reader will not easily cavil at the patient and good-natured, though exuberant egotism, which brings back to our view 'the form and pressure' of a time long past. The habits and humours, the mode of acting and thinking, which characterized a Gascon gentleman in the sixteenth century, cannot fail to amuse an enquirer of the nineteenth; while the faithful delineation of human feelings, in all their strength and weakness, will serve as a mirror to every mind capable of self-examination. But if details, otherwise frivolous, are pardoned, because of the antique charm which is about them, no excuse or even apology, of a satisfactory kind, can be devised for the gross indelicacy which frequently deforms these Essays; and as Montaigne, by an abundant store of bold ideas, and a deep insight into the principles of our common nature, deserves to be ranked high among the great men of his own original age, he also deserves the bad pre-eminence, in love, at once of coarseness and obscenity.

The desultory, careless mode, in which the materials of the Essays are arranged, indicates a feature in the author's character, to which his style has likewise a resemblance. With him, more than with any other, words may be called the garment of thought; the expression is frequently moulded to fit the idea, never the idea to fit the expression. The negligence, and occasional obscurity of his manner, are more than compensated by the warmth of an imagination, bestowing on his language a nervousness, and often a picturesque beauty, which we should in vain seek elsewhere.

From the perusal of those Essays, it is natural to infer, that the author must have studied men, not only in the closet but the world. Accordingly, we find, that Montaigne had travelled over France, entertained the King in his chateau, and more than once visited the court, where Charles IX. gratified him by spontaneously bestowing the collar of the order of St. Michel. After the first publication of his Essays, he did not long continue stationary. In this case, however, the desire of viewing foreign countries was but secondary to that of freeing himself from a nephritic disorder which had afflicted him for several years, and which, having no faith in physicians, he sought to alleviate by the use of mineral waters. With this intention he left home in 1581, and, attended by several of his friends, traversed Lorraine, Switzerland, Bavaria, and Italy. From the baths of Plombiere, Baden, and Lucca, he came to Rome, where, among other honours that awaited him, he received the freedom of the city, and soon afterwards received intelligence that his countrymen of Bourdeaux had elected him their mayor.* At the King's command, he returned from Italy to undertake this office; and his constituents signified their approbation of his conduct in it, by continuing his appointment for another two years.

The remaining portion of Montaigne's life was chiefly spent in revising his Essays. It was disturbed by the tumults of the League, and finally by the ravages of the pestilence, which compelled him for a short period to leave his home. One of his last journeys was to Paris, for the publication of his works; and during his return, he remained some days at Blois, to witness the proceedings of the States-General assembled there in 1588. He is said to have predicted to his friend, the famous de Thou, that Henry IV. would embrace the catholic religion, and restore peace to France.

But the use of mineral waters had not banished Montaigne's hereditary distemper; and his constitution, weakened by it, was unable to sustain the attack of an inflammation of the throat, which seized him in September, 1592. On the 17th of that month, the disorder had deprived him of the use of speech; but as his mental faculties remained unimpaired, he desired his wife, in writing, to send for certain of his neighbours, that he might bid them farewell. After the arrival of these persons, mass was said in his chamber. At the elevation of the host, Montaigne, with an effort, raised himself upon his bed, and, clasping his hands together, expired in that pious attitude. He had almost completed his sixtieth year.

The character of Montaigne is amply delineated in his Essays. On contemplating this picture, we are surprised to find the principles of a stoic incongruously mingled with the practice of an epicure; and the *pillow of doubt*, upon which, during the flow of health, he professed to repose, exchanged in sickness for the opiates of superstition. But notwithstanding these inconsistencies, it is impossible to avoid admiring the continued benignity and pensive gaiety which distinguished his temper. The amiableness of his private live is attested by the fact, that under the five monarchs who, during his time, successively swayed the sceptre of a kingdom torn with fanatical divisions, his person and property were always respected by both parties; and few, at an advanced age, can say, like him, that they are yet untainted with a quarrel or a law-suit.

His Essays have been abridged, translated, and given to the world in various shapes. The most valued edition is that of London, 1724, in which the original expressions are scrupulously retained, and ably illustrated by the notes of M. Coste. (T. C.)

MONTAGU, (Lady Mary Wortley) the eldest daughter of Evelyn Pierrepont, earl, and afterwards duke of Kingston, was born at Thorseby, in Nottinghamshire, about the year 1690. Though four years afterwards she lost her mother, the Lady Mary Fielding, daughter of William, Earl of Denbigh, her education was conducted with all the care which so promising a genius seemed to deserve. In addition to the usual accomplishments, she easily gained from the preceptors of her brother, Viscount Newark, a considerable knowledge of the Greek and Latin languages, to which she soon added French and Italian. The famous Gilbert Burnet, Bishop of Salisbury, is said to have guided and encouraged her more advanced studies; a manuscript translation of Epictetus, which she executed during a week, in the summer of 1710, yet bears the corrections of that distinguished prelate.

Whilst making acquisitions, at that period so rare among persons of her sex and rank, the young lady continued principally at Thorseby, or at Acton, near London. In these narrow circles her liveliness and spirits were already no less remarkable than her learning. Mrs., or as we should now say, Miss Ann Wortley, daughter of the Honourable Sidney Montagu, seems to have been her most intimate associate; and this early friendship gave rise to her acquaintance with a son of the same nobleman, Edward Wortley Montagu, to whom, after two years, she was privately married, on the 12th of August, 1712. The valuable, though not brilliant qualifications of this gentleman, were long exercised in Parliament, where his graceful manner and knowledge of business secured him considerable influence. At the period of his marriage, the fathers of both parties being alive, he could not offer his wife such an establishment as to permit her accompanying him to London during his political engagements: for the first three years of their union she lived chiefly at Warncliffe-lodge, near Sheffield. But, after the death of Queen Anne, in 1714, when Charles Montagu, who conveyed the intelligence of that event to George I. had been raised from the dignity of baron to that of earl Halifax, and farther created first lord of the treasury, that nobleman did not overlook the services of his cousin Mr. Wortley, who soon obtained the appointment of commissioner in the same department. The nature of his office placed him in connection with the court; and the appearance of Lady Mary, who now first visited that scene, attracted universal admiration. Her beauty and genius were praised, her conversation was coveted by the highest ranks of the nobility, and a more honourable tribute was paid to her talents in the esteem which she obtained from Pope and Addison.

The short-lived pleasures of such a scene had scarcely yet found time to lose their novelty, when Lady Mary was called to visit objects of a far more diversified and striking nature. In the summer of 1716, Mr. Wortley resigned his situation at the Treasury-Board, in consequence of an appointment to occupy the place of Sir Robert Sutton, Ambassador at Constantinople, who had been removed to Vienna, and directed to co operate with his successor, in endeavouring to terminate the war between the Austrians and Turks, which at that time raged with extreme violence. In the month of August Mr. Wortley left England, and his lady did not hesitate to accompany him in a journey, which, though tedious, and not without hazard, promised to offer such a field for observation and enjoyment, as great skill in modern languages, and considerable acquaintance with classical antiquities, rendered her well qualified to profit by. After leaving Holland and Germany, the embassy continued two months at Adrianople. Sultan Achmed III.,

* About fifty years ago, a manuscript account of this journey was accidentally found in the chateau which Montaigne inhabited. Being ascertained to be his composition, it was published in 1774. But neither the curiosity attached to every thing which bears the name of Montaigne, nor the learned notes of M. Querlon, are sufficient to make us relish the insignificant and often disgusting contents of a work, that seems never to have been at all intended for meeting general inspection.

whom they found here, is said to have shown a more frank disposition, and less solicitude about the Koran, than usually happens with a Turkish prince. To this circumstance it is generally ascribed, that Lady Mary was enabled to augment her acquaintance with eastern manners, by an examination of the Haram, never before or since permitted to any European.

The knowledge which she gathered respecting the habits and character of this people was minute, her mode of communicating it lively and entertaining. But Europe, in general, owes to her residence in Turkey a much more solid advantage than any such entertainment. Whilst passing the summer months at Belgrade, not far from the shore of the Bosphorus, Lady Mary had occasion to observe a custom practised by the peasants, which was said to guard them from the effects of small-pox, a dreadful, and, at that time, cureless malady. She examined the process of ingrafting, or inoculation, as it was afterwards called, became convinced of its efficacy, and with a courage for which humanity is deeply indebted, she consented to have the operation tried upon her son, at that time about three years old. Edward Wortley Montagu, afterwards so celebrated for his rambling, eccentric character, sustained the experiment, without hurt, in the month of March, 1718. The event encouraged his mother to form the hope of establishing a practice so salutary in her own country. It is well known that, after a lapse of some years, the zealous support which she bestowed on the attempts of Mr. Maitland, her physician, to introduce inoculation, on his return to England, was at length crowned with success. In 1721, government allowed five criminals to avoid the sentence of death, by submitting to this process; the successful experiment was sanctioned by the College of Physicians; inoculation obtained the patronage of the Royal Family, and had finally triumphed over all opposition, when, eighty years afterwards, the more precious discovery of Jenner promised entirely to extirpate the disorder.

Lady Mary was not long detained from the society of her friends in England. Mr. Wortley's conduct was approved of both by the Courts of St. James and Vienna; but, owing to the exorbitant demands of the latter, his negotiations entirely failed. His letters of recal, countersigned by Addison, are dated 21st October, 1717; and on the following 5th of June, he and his family commenced their journey to Britain, where, after visiting Tunis, Genoa, Lyons, and Paris, they arrived on the 30th of October, 1718.

At the Court of George I., Lady Mary was received with increased distinction. The celebrity arising from her travels, the fund of new ideas acquired in the course of them, the graphical and spirited mode in which she described what she had seen, gave a new charm to her already fascinating conversation. She obtained particular notice from the Princess of Wales, afterwards Queen Caroline, and by her brilliant acquirements excited the praise or the envy of every competitor for such honours as the admiration of a court can bestow. The excellence of her sprightly conversation had already been stamped by the approbation of Pope; and at her return from Turkey, the poet appears to have manifested the continuance of that friendship which his lively, though rather affected letters, had so warmly expressed during her absence. He earnestly invited her to take up her residence at Twickenham, and had the pleasure of successfully negociating a lease of Sir Godfrey Kneller's house for her reception. In this celebrated village, Lady Mary could occasionally exchange the gaieties of fashionable life at London for the company of those celebrated characters who frequented the society of Pope, and diversify the flatteries of Dr. Young and her second cousin, Henry Fielding, by the conversation of Swift, Gay, and Arbuthnot.

But the friendship of wits is proverbially fragile. In the case of Pope and Lady Mary, its existence, rendered precarious by the conflicting claims of a vanity, which on both sides sought gratification in the dangerous province of satire, was shortened by political hostility. Dissatisfied with the quantity of praise which the world bestowed on Pope for correcting her productions, and which the poet, it was thought, did not steadily enough refuse, Lady Mary had for some time omitted consulting him on such occasions; and this coldness was increased at the accession of George II. by her avowed partiality for Sir Robert Walpole, and her intimacy with Lord Hervey, which could not but offend a professed follower of Bolingbroke. The publication of the *Town Eclogues* completed this alienation. Lady Mary had several years before submitted these poems to Pope's inspection, and as the satire or scandal they were supposed to contain rendered them an object of general curiosity, copies were extensively circulated, and to print them became a fit speculation for the noted Edmund Curl. In spite of remonstrances and threats, the work came out under Pope's name; and Lady Mary, defrauded of praise, and suspecting collusion, not only renounced all intercourse with him, but displayed the resentment of forfeited friendship in bitter sarcasms, which were too faithfully reported to the object of them. The irritable nature of Pope was little calculated to brook such treatment. His opinion of Lady Mary, under the name of Sappho, expressed in his satires with more rancour than taste or wit, called forth from his victim, and her coadjutor, Lord Hervey, also stigmatized under the name of Sporus, those "verses addressed to the translator of the first satire of the Second Book of Horace," the private circulation of which produced a letter from Pope to his antagonists, disavowing any such intention as the one imputed to him. Much has been said of the malignity displayed by Pope in this attack, and of the meanness with which he attempted to recede from it. Certainly the accusations brought against Sappho are of a character sufficiently black, and the author's equivocal statements about their application seem to argue considerable weakness of mind; but, if without investigating how far such accusations might be founded on truth, we condemn the man who, under the mask of a moralist, stoops to gratify his individual hatred, we are compelled at the same time to admit, that his antagonists appear to have wanted the power rather than the will, to be equally barbarous. It is matter of regret, that the friendship of Pope and Lady Mary was converted into enmity: but the means adopted by the one party to satisfy that enmity were hardly less blameable than those adopted by the other. A fierce, though dull execration of Pope's malice and deformity, is but awkwardly blended with censures of his virulence and coarseness.

The quarrel with this formidable satirist produced disagreeable results for Lady Montagu. It no doubt contributed to spread those black reports about her character and conduct, to which the many victims of her sarcastic pleasantry were at all times willing listners.

She still lived at court with the great and gay, sharing or directing their amusements, admired for the pungency of her wit, and the sprightliness of her occasional verses, but her life seems not to have been happy. To other sources of solicitude, ill health was at last added; and in 1739, with Mr. Wortley's consent, she resolved to fix her abode in Italy. Passing through Venice, where much respect was shown to her, she visited Rome and Naples, and after having spent several months at Chamberry and Avignon, she finally settled at Brescia. From this city, she afterwards removed to Lover, on the northern shore of the Lake Iseo, for the benefit of its mineral waters; where, having purchased and refitted an elegant house, she divided her attention between reading and managing the concerns of her vineyard. With a small and select society, she seems to have enjoyed more contentment in this retired situation than her former habits would have led us to expect. About the year 1758, however, she exchanged her solitude for the amusements of Venice, in which city she remained till 1761, the period of Mr. Wortley's death. She then yielded to the solicitations of her daughter, the Countess of Bute, and after an absence of twenty-two years, she returned to England in the month of October. But her health had suffered much, and a gradual decline terminated in death, on the 21st of August, 1762.

Overawed by Pope and his associates, Lady Mary had ventured to publish nothing during her lifetime. The Town Eclogues, above alluded to, were printed under Pope's name, and though his editors have continued to assign the "Basset Table," with the "Drawing Room," to him, and the "Toilet" to Gay, she seems, in fact, to have been the author of them all. Several of her other poems had appeared in different collections, but it was without her permission. If we may judge, however, from an expression employed in writing to her sister, the Countess of Mar, it would seem that Lady Mary contemplated the posthumous publication of her letters; and, towards the conclusion of her residence in Italy, she had actually transcribed that part of them which relates to Mr. Wortley's embassy. The manuscript, entrusted to Mr. Lowden, a clergyman at Rotterdam, was surreptitiously printed by Beckett in 1763; and the curiosity which it had long excited in the world, was finally gratified by the publication of all her poems and letters in 1803. The edition, undertaken at the request of her grandson, the Earl of Bute, was superintended by Mr. Dallaway, who prefixed to it a life of the author.

Concerning the merits of Lady Montagu's poems, it is not necessary to say much. Suggested chiefly by ephemeral topics, they seem to have been written without great care. They are not polished, but across their frequent harshness and infelicity of expression, we can easily discern considerable vivacity of conception, accompanied with some acuteness in discriminating character and delineating manners. It is to be regretted that they are not always free from indelicacy.

But Lady Mary's principal merit is to be sought for in her letters. Those written during the embassy were loudly applauded at first, and they have since maintained a conspicuous place in this still scanty department of English literature. The official character of Mr. Wortley procured her admittance to whatever was splendid or attractive in every country which they visited. She seems to have been contented with herself, and therefore willing to be pleased with others; and her cheerful, sprightly imagination, the elegance, the ease, and airiness of her style, are deservedly admired. Succeeding and more minute observers have confirmed the accuracy of her graphic descriptions. Her other letters are of a similar stamp. The continual gaiety, the pungent wit, with which she details the passing follies of a court, but too successfully imitating that of Louis XV., render her letters extremely amusing. In those written from her retirement at Lover, we discern the same shrewdness of observation, with a little more carelessness of expression. The pensive, calm regret which they breathe, and, above all, the tender affection for her daughter, the Countess of Bute, to whom they are generally addressed, perhaps more than compensate for the absence of that flow of spirits and exuberance of incident, which distinguished the correspondence of her youth. In a literary point of view, Lady Mary's writings certainly do not belong to a very elevated class, but they occupy the first rank in their class. Considering the times and the circumstances of the writer, they may safely be called extraordinary. And, though the general diffusion of knowledge within the last century has rendered it common for females to write with elegance and skill upon far higher subjects, Lady Mary deserves to be remembered as the first English woman, who combined the knowledge of classical and modern literature with a penetrating judgment and correct taste. (T. C.)

MONTAUBAN, a town of France, and the capital of the department of the Tarn and Garonne. It is situated upon elevated ground on the Tarn, which pursues a winding course beneath it, through meadows and woods. It consists of the old and new town, on the right bank of the Tarn, and of the Ville de Bourbon, on the left, the communication being made by a bridge of brick. The streets and houses are in general good. The square in the centre has good buildings of painted brick, with a double range of arcades. From this square eight streets diverge. The chief public buildings and establishments are, the cathedral, the bishop's palace, the ci-devant college of the Jesuits, an observatory, a society of arts and sciences, and a public library. The Protestant university, suppressed in 1629, was re-established by Bonaparte in 1810, and has four professors of divinity. The chief manufactures of the place are, silk stuffs, stockings, linens, serge, and woollen stuffs. From the elevated public walk, called the Falaise, there is a splendid view over one of the finest plains in France. The view extends to the distance of 30 leagues, and is terminated on one side by the sea, and on the other by the Pyrennees. Population of the town, 24,000, about half of whom live within the walls. The position of the observatory is in East Long. 1° 20′ 45″, and North Lat. 44° 0′ 55″.

MONT BLANC. See Blanc.

MONTESQUIEU, (Charles de Secondat, baron of) and likewise of la Brede, was born at the mansion-house of the latter estate, near Bordeaux, on the 18th of January, 1689. His father, at one time a soldier, had soon relinquished that profession: and young Montesquieu was early destined to the bar, from which his paternal grandfather and uncle had successively risen to the dignity of *president à mortier** in the parliament of their native province. His education was carefully attended to;

* Vice President. *A mortier* relates to the species of cap worn by that officer.

and the flattering presages of childhood being in this case followed by judicious management, were afterwards completely verified. On the 24th of February, 1714, he became an advocate in the parliament of Bordeaux; and the office of *president à mortier* in that court was consigned to him by the uncle already mentioned, on the 13th of July, 1716. He also inherited the property of that relation, who had lost an only son.

The new president sustained the reputation which his predecessor had acquired. His colleagues showed what opinion they entertained of his address and integrity, by charging him with the remonstrance, which they judged it proper to make, against the imposition of a new tax, during the minority of Louis XV. in 1722. This delicate task he successfully accomplished.

But the attainment of professional honour was not the chief object of Montesquieu's ambition. Following the instinctive bent of genius, he was unwearied in acquiring general knowledge; and his vigorous mind seems, at an early period, to have conceived the germ of those ideas, which he afterwards so brilliantly developed in his writings. Before the age of twenty, he had studied, with higher views than those of a mere lawyer, the voluminous works which treat of Roman jurisprudence: his regular abstract of their contents was probably the groundwork of the *Esprit des Lois*. But though already cherishing the hope of fame, he felt no impatience to show himself before the world. It was not till the age of thirty-two, that his first production, the *Lettres Persanes*, was given to the public in 1721, without the author's name. If the *Siamois*, of Dufreni, or the *Espion Turc*, suggested the plan of this work, its execution is entirely original. "The delineation of oriental manners," says d'Alembert, "real or supposed, of the pride and the dulness of Asiatic love, is but the smallest of the author's objects; it serves only, so to speak, as a pretext for his delicate satire of our customs; and for other important matters which he fathoms, though appearing but to glance at them." The work was generally read and admired; but some censures bestowed upon the conduct of Louis XIV. caused it to be regarded with an evil eye at Court; and one or two sarcasms levelled at the Pope awakened the zeal of such as were rigidly devout, or found it convenient to seem so. The author was industriously represented as a man equally hostile to the interest of religion and the peace of society. Those calumnies reached the ear of Cardinal de Fleury; and when Montesquieu, sustained by the public opinion of his talents, applied for the place which M. Sacy's death had left vacant in the French academy, that learned body was made to understand, that his majesty would never give his consent to the writer of the *Lettres Persanes*; because, though his majesty had not read the work, persons in whom he placed confidence had shown him its poisonous tendency. Without feeling too much anxiety for literary distinction, Montesquieu perceived the fatal effect that such an accusation might produce upon his dearest interests. He waited upon Fleury, therefore, and signified, that although for particular reasons he had not acknowledged the *Lettres Persanes*, he was very far from wishing to disown that work, which appeared to contain nothing disgraceful to him, and which ought at least to be read before it was condemned. Struck by these remonstrances, the cardinal perused the work; the objections were removed; and France avoided the disgrace of forcing this great man to depart, as he had threatened, and seek among foreigners, who invited him, the security and respect which his own country seemed little inclined to grant.* The 24th of January, 1728, is the date of his admission; and the inaugural discourse pronounced by him on that occasion appears to have been distinguished by that originality for which all his writings are remarkable.

A short time before this event, Montesquieu had quitted his judicial charge. Full of the important ideas which had long occupied his attention, he determined to renounce every engagement which might obstruct the perfection and publication of them. To qualify himself for the arduous task of investigating and appreciating the different political or civil constitutions of ancient and modern times, he judged it requisite to travel—that, so far as possible, he might study the manners and character, the physical and moral condition of the European nations, by actual inspection. In pursuance of this object, he set out for Vienna, along with Lord Waldegrave, the English ambassador. From this city, after conversing with the celebrated Prince Eugene, and surveying all that seemed worthy of notice, he passed into Hungary, and afterwards to Italy, where he met with Lord Chesterfield, and travelled in his company to Venice. Here he found our noted countryman, John Law, still fostering magnificent projects, though reduced to gain a precarious livelihood by often risking his sole possession, a diamond, at the gaming table. Whilst examining the singular institutions of this republic, and canvassing the subject with eager frankness in places of public resort, Montesquieu, being informed by a friend that the government took offence at his procedure, was cautioned to withdraw, if he wished to avoid a scrutiny which might be troublesome, and perhaps dangerous. He instantly embarked for Fucina, where he arrived in safety, though not till, in his fear of being overtaken by some gondolas which appeared to aim at reaching the ship, he had consigned his manuscript remarks to the waves.† He next visited Rome; and having surveyed Switzerland and the United Provinces, he repaired to this country in 1730. Newton and Locke were dead; but the philosophical traveller found men in England qualified to estimate his talents; respected and patronized by Queen Caroline, he enjoyed the intimacy of Pope, Bolingbroke, and many other eminent characters of that period.

From England, Montesquieu returned to La Brede. The striking scenes which he had examined, and the distinguished persons with whom he had associated, could not but furnish matter of deep and extensive re-

* Voltaire represents this matter in another light. "He (Montesquieu) adopted a skilful artifice to regain the minister's favour; in two or three days he prepared a new edition of his book, in which he retrenched or softened whatever might be condemned by a Cardinal and a minister. M. de Montesquieu himself carried the work to Fleury, no great reader, who examined a part of it: this air of confidence, supported by the zeal of some persons in authority, quieted the Cardinal, and Montesquieu gained admission to the Academy." *Ecrivains du Siècle de Louis XIV* § *Montesquieu*. The authenticity of this statement, however, appears to rest solely on Voltaire's evidence, not altogether unexceptionable in the present case. D'Alembert's account is generally preferred.

† In the *Dictionnaire Biographique*, this affair is said to have been a mere frolic, invented and executed by Lord Chesterfield, to convince Montesquieu of his error in maintaining that French *vivacity* was preferable to English *good sense*. But his Lordship's logic, as well as urbanity, must have left him, before he could make use of such an argument. The statement seems to be incredible.

flection to a mind so gifted. Perhaps his well known observation, that Germany is a country fit to travel in, Italy to sojourn, England to think, and France to live in, exhibits rather more pointedness than truth; but the practical knowledge which he had acquired respecting men and governments, was advantageously applied in his future productions. The first, in order of time, is an Essay, *Sur les causes de la Grandeur et de la Décadence des Romains*, completed during the two years of his seclusion at la Brede, and published in 1734.

In attempting to derive the grandeur and downfall of Rome from the admitted principles of human nature, Montesquieu gave a new turn to such investigations. If some elements of a problem so complex have been omitted, and others rated too high or too low, the work must be allowed to exhibit views of political society, at all times specious, often equally just and profound: the vivid pictures, the acute and original thoughts, with which it every where abounds, are to be traced in many succeeding speculations. It deserves praise also for the manly and liberal tone of feeling that pervades it.

But the chief basis of Montesquieu's fame is the *Esprit des Lois*, published in 1748. His profession had led him to examine the subject of law with great minuteness; and he appears, from an early period, to have aimed at discovering some system which might serve to connect the isolated facts of a science, the extent and confusion of which increased with his knowledge of it. Hitherto, writers on jurisprudence had limited their views to the codes of particular states, or to metaphysical discussions concerning the abstract rectitude of those codes. But the object of Montesquieu was different, and much more comprehensive. Embracing the various, and apparently capricious systems of law, as they regard commerce, religion, or civil rights, in every country which travellers or historians make known to us, he endeavours to elicit regularity from this chaos, and to derive the intention of each legislator, or at least the utility of his law, from some circumstances in the natural or political situation of those to whom it is addressed. The attempt, if not entirely successful, was arduous and vast: it was likewise altogether new. The reading alone which it presupposes would have deterred a man of common ardour; especially if, like the author, almost totally deprived of sight, he had been compelled to employ the eyes of others. But although the *Esprit des Lois* cannot be regarded as a full and correct solution, it is at least a splendid theory; and the labour of twenty years devoted to produce it, the enthusiasm required for sustaining such an effort, were by no means misapplied. The abundance of curious, and generally authentic information, with which the work is sprinkled, renders it instructive even to a superficial reader; while the vigorous and original ideas to be found in every page of it, by an attentive one, never fail to delight and astonish where they convince, and to improve even where the truth of them seems doubtful. The brilliant hints, correct or otherwise, which the author scatters round him with a liberal hand, have excited or assisted the speculations of others, in almost every department of political economy; and Montesquieu is deservedly mentioned as a principal founder of that important science. The merits of his work are farther enhanced by his style, which, though emphatic and perspicuous, rather than polished, abounds in elegant sarcasm, in vivid and happy turns of expression, which remind us of his countryman, Montaigne.

Among the defects of the *Esprit de Lois* may be numbered its want of method, partly apparent, partly real. The transitions are universally abrupt; the brevity sometimes degenerates into obscurity, and the smartness into affectation. Though the author's tone is always decided and positive, his statements and speculations are occasionally uncertain or erroneous: in particular, the effects attributed to climate (some of which may have been borrowed from Bodin's *Methodus Historiæ*) are greatly exaggerated. But whatever blemishes the work may have, it is entitled to the high praise of steadily supporting the cause of justice and humanity, without departing from the moderation and reserve proper in combating established prejudices.

The reputation which its author had already gained, procured for the *Esprit de Lois* a sufficient degree of attention; but the work, on its first appearance, was very unfavourably received. Such as were unable or unwilling to relish the deep philosophy of its matter, attached themselves to the blemishes of its manner, and affected to despise it. The Chancellor Daguesseau observed, that it should have been denominated *De l'esprit sur les lois*; and the pun obtained a circulation far above its merit. Voltaire also, being one day visited by the Abbé Olivet, whilst perusing the work, exclaimed, *Venez, L'Abbé, venez, lire Arlequin Grotius**. The general voice of Europe, indeed, soon put such criticisms to silence; but it was only to excite others of a graver and more dangerous nature. The Editor of the Gazette Ecclesiastique, long deeply engaged in the Jansenist quarrels which agitated France for many years, assailed the author of the *Esprit des Lois*, in two pamphlets, with the charge of deism, and the weightier, though contradictory one, of following the doctrines of Spinosa. The defence which Montesquieu published, admirable for its strain of polite irony, candour, and placid contempt, was entirely triumphant. Indeed, abilities of a much lower order than his, would have sufficed to cover with ridicule the weak and purblind adversary, who discovered the source of the *Esprit des Lois* in the *Bull Unigenitus*, and blamed his opponent for neglecting to examine the doctrines of grace and original sin. It is to be wished, that Montesquieu had employed means as legitimate to counteract Dupin's criticism. His admirers would willingly forget, that when a copy of this work, now ready for circulation, fell into his hands, he carried it to the royal mistress, Madame Pompadour, and allowed her to inform Dupin, that as the *Esprit des Lois* enjoyed her special favour, all objections to it must be instantly suppressed.

Some excuse for this part of Montesquieu's conduct may perhaps be found in the growing infirmity of his health, which rendered him daily less capable of enduring the vexation of such contests. In fact, the chagrin already produced by them, the effects of study, and the civilities of the great, who courted his society with an eagerness which he felt would be fatal, had

* This anecdote is reported by M. Suard, who had it personally from Olivet. If Voltaire really used the epithet in question, it must not be considered as expressing the deliberate opinion which that extraordinary person had formed of the *Esprit des Lois*; to the author of which, notwithstanding their mutual dislike, he pays a just and elegant tribute, in the discourse read at his admission into the Academy.

gradually undermined a constitution, at no time very robust. In the beginning of February 1755, he was seized with an inflammation of the lungs, which soon proved mortal. His last days were soothed by the sympathy of all ranks of men: and though loaded with the most cruel pains, far from his family, and insulted by the officious visits of Father Routh (an Irish Jesuit, who afterwards forged a letter in his name), the peace and equality of soul which had marked the tenor of his life did not forsake him at the close of it. He expired on the 10th of February, aged 66 years and a few days.

The private character of Montesquieu appears to have been such as the perusal of his works might lead us to anticipate. Possessing that calm independence which secured him respect, he possessed also that mildness and benignity of character which displayed itself in a cheerful temper, and obtained him universal love. He was distinguished by the readiness which he always manifested to use his influence with the government, in behalf of persecuted men of letters: and strict frugality frequently enabled him, without impairing the property of his family, to mitigate the wants of the indigent.

A multitude of anecdotes attest the extent of his colloquial powers. The number of nations and celebrated men whom he had seen, the vigour of his mind, its boundless fertility in original and lively ideas, rendered his conversation at once instructive and fascinating. It was curt, like his style, without bitterness or satire, yet full of attic salt, to which his Gascon accent perhaps added new charms. The frequent absence of mind, for which he was remarkable, never occurred in a serious or interesting discussion: it was not affected; and he constantly awoke from it by some brilliant sally fitted to revive the conversation. Though living with the great, and formed to delight the most polished circles, he could yet derive information and pleasure from the simplest objects, and felt at all times happy to exchange the splendid bustle of Paris for books and repose at La Brede. It must have been a striking spectacle to see this teacher of philosophers, seated beneath an oak in his pleasure grounds, and in order to relax his mind from the studies which he never carried to excess, conversing gaily with a crowd of peasants in their own patois, adopting their views, investigating their genius, supremely happy if his influence could terminate their disputes, or solace their troubles. His touching interview with the Marseillese artisan; his delight on learning that this young man devoted every evening to ply as a boatman for the ransom of a father captive in Barbary; his generous and delicate reward of such affectionateness have been made the subject of a drama entitled *Le Bienfait Annonyme*.

Montesquieu, in 1715, had married Demoiselle Jeanne de Lartigne, whose father, Pierre de Lartigne, was Lieutenant-Colonel in the regiment of Maulévrier. She bore him two daughters and a son. The latter, Jean Baptiste de Secondat, less noted for his respectable talents, than for the abstraction of his manners, wrote several tracts on commerce and natural history. He frequently resided in London, where some of his works were published. He died at Bourdeaux in 1796, aged 80 years.

Besides the works above enumerated, Montesquieu is author of the *Temple de Gnide*, which quickly followed his *Lettres Persanes*. The *Pensées Diverses*, collected from his manuscripts, was published in 1758; the *Lettres Familières* in 1767. None of these productions are destitute of genius, but they cannot add much to the reputation of a man otherwise so distinguished. His works have all been translated into English. The best edition in the original language is thought to be that of Paris, 1796, 5 vols. 4to, or that of Bâle, 1799, 8 vols. 8vo. (T. C.)

MONTE VIDEO, a town of South America, in the province of Buenos Ayres, situated on a gentle eminence on the north side of the river Plata. The town occupies the whole of the promontory that forms the east point of the harbour. The houses, which are generally only one story high, with flat roofs, are built of stone and brick. The town having an elevated situation, and the houses being interspersed with gardens and trees, has a fine appearance from the harbour. The public buildings are, the cathedral, which is handsome; the town-house, and the prison, which are situated in the great square. There is a lighthouse on the mountain, which overlooks the town, and gives it its name. The town is defended by regular stone fortifications, which enclose the whole peninsula. The trade consists in hides, tallow, and dried beef. Coarse copper from Chili, in square cakes, is sometimes shipped here. West Long. 56° 14′ 38″, and South Lat. 34° 54′ 48″. For a full account of the history of the place, and of the province, see BUENOS AYRES.

MONTFAUCON, BERNARD DE, a celebrated French antiquary, was born at Soulage, in Languedoc, on the 17th of January, 1655. His parents, distinguished among the nobility of those parts, usually resided at the chateau of Roquetaillade, where he lived till the age of six years. His education was then entrusted to the *Pères de la doctrine Chrétienne* at Limoux, under whose direction his zeal and assiduity were rewarded by a suitable progress in classical learning. Before leaving the paternal roof, his taste for reading had attracted the notice of Pavillon, Bishop of Aleth, who predicted the young man's future eminence; and in this new seminary, the perusal of Plutarch is said still farther to have excited his enthusiasm. Yet the promises of that early age at first seemed likely to be disappointed. Montfaucon adopted the profession of arms, and the contemplation of classical antiquity was exchanged for active service in the wars of Germany, under Marshal Turenne. But the character originally impressed upon Montfaucon's genius, though obscured, was not obliterated: the death of his parents, the loss of his superior officer, inspired disgust at the military life; he quitted the regiment of Perpignan in 1675, after serving two campaigns (in which it does not appear that his conduct was marked by any thing but the fighting of a duel), and entered the congregation of St. Maur, where, having spent the necesssary period of probation, he assumed the habit of a Benedictine.

In that tranquil scene, his love of study revived in proportion to the abatement of melancholy; and his theological pursuits were mingled with the investigation of antiquity. The fruit of these researches was manifested in 1688, by the publication of his first original work, *La verité de l'Histoire de Judith*, which involved an account of the Median and Assyrian empires, and a critical dissertation concerning that history of the latter, which is commonly attributed to Herodotus.

The reputation for learning which this treatise acquired, enhanced by several compilations, and particularly by his edition of St. Athanasius' works, published ten years afterwards, procured him a favourable reception in the various parts of Italy, to which his love of antiquarian studies led him, in 1698. At Rome, he officiated as procurator of his order; the Pope and Cardinals were lavish in their attentions; and Montfaucon, during the intervals of his ecclesiastical functions, gave frequent and unequivocal proofs of the learning which he possessed, and was anxious to augment. It is related, that Zacagni, then sub-librarian of the Vatican, feeling his vanity wounded by the praise bestowed on this accomplished foreigner, laid several schemes to lower him in the public estimation. One day, whilst Montfaucon, among a crowd of distinguished persons, happened to be sauntering in the library, Zacagni, with affected politeness, requested the antiquary to favour him with the date of a Greek manuscript, which he spread out before him. Montfaucon replied, that apparently it was written about 700 years ago; his antagonist, with a triumphant sneer, desired him to observe the name of Basil, the Macedonian, written at the top; the Frenchman asked if it was not Basil Perphyrogenitus, later by 150 years; and as this, upon examination, proved to be the case, Zacagni retired with his manuscript, and thenceforth left the stranger at peace.

On his return from Italy, in 1702, Montfaucon published the *Diarium Italicum*, which, besides a learned account of the antiquities he had visited, was farther enriched by some ancient Greek and Latin treatises, now printed for the first time. It deserves to be remarked, that this work was translated into English about twenty years afterwards, by the noted Orator H nley, whose 'gilt tub,' and whose labours in it, as 'the Preacher and the Zany of his age,' have been immortalized in the Dunciad of Pope.

After the period of his return from Italy, Montfaucon's life was marked by nothing but the successive appearance of his writings. The *Paleographia Græca*, exhibiting rules to determine the age of Greek manuscripts, appeared in 1708; and his great work, *L'Antiquité Expliquée*, in 10 vols. folio, Latin and French, was published in 1719, and followed by a supplement of 5 vols. in 1724. The book (of which this edition is still reckoned the best) contains above 1200 plates; and though many of them are only copies of inaccurate originals, and though the whole seems to bear evident marks of haste, it was regarded as a very extraordinary effort, and continues yet to be a mine from which other less laborious inquirers draw their information. After the *Monumens de la Monarchie Françoise*, 5 vols. folio, came out in 1729, Montfaucon spent the rest of his life chiefly in revising his foregoing productions. Except the publication of his *Bibliotheca Bibliothecarum*, it was marked by no incident worth recording; and two years after that event, he died suddenly at Germain-des-Près, on the 21st of December, 1741.

Montfaucon was celebrated for the mildness and benignity of his character. Neither the favours which he had received from an emperor, nor the honours with which he was decorated by two successive popes, could at all abate his humility; and strangers who conversed with him, returned not more surprised at the amazing extent of his information, than at the unpretending simplicity of his manners. Of an author who has left 44 vols. folio, it may be expected that elegance will not be a characteristic; and, accordingly, Montfaucon's writings are blamed for their cumbrous style and defective arrangement; but his erudition, a quality more befitting such pursuits, has never been called in question; and his works are still looked up to, as guides through that obscure and intricate department of knowledge which he devoted his life to study. (T. C.)

MONTGOMERYSHIRE, an inland county in North Wales, on the north touches on Denbigh and Merionethshires; from the former, it is in part divided by the river Tannatt; on the south, it is bounded by Radnorshire; on the west, by Merionethshire and Cardiganshire; and on the east, by Shropshire. It measures in length from north to south about 35 miles, and in breadth, from east to west, 30 miles. It is the largest county in Wales, measuring, according to Templeman, 444.800 acres; and, according to Evans, 491,000 acres. Of these, only 60.000 are arable, 180,000 are under pasture, and the rest are in a great measure waste and uncultivated. It is divided into nine hundreds, and contains 47 parishes, and seven market towns, viz. Montgomery, a borough, and the county town; Welspool, Llanfyllin, Llanfair, Machynleth, Newtoun, and Llanydloes. It returns two members to Parliament, one for the shire, and one for Montgomery; is in the province of Canterbury, and dioceses of St. Asaph, Bangor, and Hereford.

This county possesses a larger proportion of fertile vales and plains than most of the Welsh counties. The vale through which the Severn flows, is by far the most considerable, and in general the most fertile; there are likewise smaller, though equally fertile vales, through which several of the tributary streams of the Severn flow. The greater part of the county, however, is mountainous, and the mountains are in general very bleak in their appearance, as well as sterile. A chain, commencing at Plinlimmon, in the south-west, and running north-west, with some deviations, till it terminates in the vale of Festiniog, may be called the back-bone of this county and Merioneth. Nearly 50 miles of this chain might be traversed without crossing a single stream; and a farm-house on it is so situated, that the rain which falls on the west side of the roof, flows into Cardigan bay, while that which falls on the east side, flows into the sea near Chester. The main streams on the west side of this chain, are the Dovey, the Maw, and the rivulet that flows through the valley of Festiniog; on the east side, are the sources of the Wye, Severn, Dee, &c. The Wye rises on the south side of Plinlimmon, and taking an east, and afterwards a south-east course, leaves the county. The Severn soon loses its character of a mountainous stream, forming large valleys, and generally flowing between deep banks. At Llanydloes, it ceases to be a torrent, and thence forms a delightful valley; as it inclines near Montgomery to the north, the valley expands, and it soon afterwards enters Shropshire, near the Brythen hills. Of the streams which join the Severn in this county, the largest are the Fyrnwy and Tannatt. The former is composed of two uniting branches of the same name, which cross the county from the west, and join the Severn near Llandrinio. The Tannatt meets it before its junction with the Severn. This latter is of the greatest importance as a navigable river, as it has a conveyance from Montgomeryshire into South Wales, through Shropshire, Worcester, and Gloucester, to Bristol. Plinlimmon has been incidentally mentioned: it lies partly in this county, and partly in Cardiganshire, belonging, however, more properly to the latter. Its perpendicular height is far inferior to that of Snowden and Cader Idris, and it is indeed a very dreary spot. The view from its summit, however, is very extensive, and in some points very grand. There is one canal in Montgomeryshire, which begins at Portymain limeworks, in Shropshire, where it unites with the Ellesmere canal. It afterwards crosses the Fyrnwy, and joins another part of the Ellesmere canal. There is a cut to Welspool, and from thence it goes parallel to the Severn, till it joins it at Newton. It is 27 miles long, besides the cuts, and the lockage is 225 feet. The soil of the valleys is principally a strong loam; that of the mountains a thin and cold clay. Limestone is only found at the termination of a ridge which runs from the north-west of Anglesey through Caernarvonshire and Denbighshire, and near the confluence of the Severn and Fernwy: on a limestone rock here, immense quantities of lime are burnt. The climate of this county varies considerably. The midland, west, and south-west parts, are very cold and ungenial, in consequence of their elevation; the climate of the valleys, and of the fine arable land that lies on the east side of the county, is mild. The strongest winds blow from the south-west and north-west. The west wind blows nine months in the year.

Montgomeryshire is rich in mineral treasures; the most important and abundant of which is lead. A considerable mine of this metal has been found at Dylipan, and another on the borders of Cardiganshire, near a copper mine, the ore of which contains much silver. An uncommonly rich lead mine was wrought many years with very great profit at Llangynnog, but it is now overpowered with water at the depth of 100 yards; it was discovered in 1692, and contained a solid rib 3½ yards thick of pure ore, affording for forty years a clear annual revenue of £2000; yielding about 4000 tons annually. There are still, however, obtained in this neighbourhood considerable quantities of lead and calamine, which are sent in their raw state to the foundries near Ruabon in Denbighshire. From the lofty rocks of Llangynnog, a considerable quantity of coarse slates is obtained. It is remarked, that the strata of these and other quarries which lie on the north side of the mountains incline to the east, while in those to the south, the ore is reversed. Slate is also procured near the junction of the Fyrnwy and Severn, and sent down to Bristol. Coal is found only at Coadwaes, on the borders of Shropshire: it burns rapidly. The Severn and its tributary streams are celebrated for the great varieties of fish which they contain; it is said that the salmon penetrates up the Severn almost as far as Plinlimmon. This county was once well covered with trees, and is still well wooded; its oak has been preferred to all others for the use of the dock-yards; in the year 1796, three oaks were cut down, which measured respectively 525, 450, and 687 cubic feet.

The agriculture of this county presents little that is interesting; in some of the vales a good system of arable husbandry is followed; in the east part of the county hemp is much grown. Few cattle are fattened; the genuine breed are bad; the best sheep are peculiar to the Corry hills; their wool is tolerably fine. The hilly tracts are almost entirely sheep-walks; "and the flocks, like those of Spain, are driven from distant parts to feed on them during the summer; the farms in the small valleys being only a sort of appendages for winter habitations and provisions." A horse peculiar to the hilly parts of this country and Merionethshire, is a small poney called myrlyn; they are very hardy and active, and well adapted for the team upon mountainous farms. The roads are far from good; from the returns to Parliament it appears that, in 1814, the length of the paved streets and turnpikes was—

	Miles.	*Furl.*

Highway rates, ...	568	0	0
Law expenses, ...	39	0	0
Total,	£5267	0	0

The principal manufactures are flannels, and other coarse cloths; the principal manufactories for flannels are within twenty miles round Welspool; at this town a large quantity is sold annually, chiefly the produce of manual labour, though latterly about forty carding and several spinning-machines have been erected. The flannels of this county are from 100 to 120, and some of them 132 yards long, and seven-eighths of a yard wide. They are sent from Welspool in a rough state to Shrewsbury, where they are finished. There is a great market for woollen yarn at Llanydloes. The following are the results of the returns relative to the poor for the year 1815:

Annual value of real property, .	£207,286	0	0
Poor and other rates, . . .	33.488	0	0
Expended for the poor, . . .	28,830	0	0

See Davis's *Agriculture of North Wales. Beauties of England and Wales*, vol. xvii. (w. s.)

MONTGOMERY, the county town of Montgomeryshire, is situated on the declivity of a hill, not far from the east banks of the Severn; it is governed by two bailiffs and a town-clerk, and returns one member to Parliament; the right of election is vested in the burgesses of the town only, who amount to about eighty; it is a small neat town. The castle was formerly a strong and majestic building; it stood on the extremity of an eminence on the north side of the town, the projecting rock being very high. During the civil wars, a general and hard contested battle took place near Monmouth, which terminated in the defeat of the royalists; soon afterwards the parliament ordered the castle to be dismantled. Till very lately Montgomery was nearly destitute of trade, but by means of its canal it now imports a vast number of various kinds of goods from Chester, and exports limestone, lead, slate, &c. The following are the population details for the year 1811:

Houses inhabited, . . .	818
Families inhabiting them, . .	924
Houses building, . . .	5
——— uninhabited, . . .	17
Families employed in agriculture,	591
——————— in trade, .	270
All others, ...	63

MONTPELLIER, MONS PESSULANUS, or MONS PESTELLARIUS, a city of France, and capital of the department of Herault, is finely situated upon a height, which it entirely covers. Its houses rise in the form of an amphitheatre, and the river Lez waters the rich plain on which it stands. The streets of the town are narrow, dark, and winding, and the squares are small, and few in number. The houses are in general black and gloomy, and the principal edifices, such as the palace of justice, the ancient bishop's palace, now the palace of the Prefecture, the hotel de ville, and the cathedral, are of a bad style of architecture. The fauxbourgs, which surround Montpellier, are nearly as large as the town itself, and conatin many good houses. The town is watered by a great number of fountains.

Montpellier is celebrated principally for its university, which was established in 1289, by Nicolas IV. who divided it into the three faculties of law, medicine, and the arts. In 1410, the faculty of theology was substituted for that of the arts. At the revolution, the university was abolished, and the faculty of medicine was established under the title of the Special School of Medicine. The school of surgery, founded by Lapeyronie, is now united with the school of medicine. During the ministry of M. Chaptal, a superb amphitheatre was constructed for it, on the model of the Museum of Natural History at Paris. The chair of the professor of anatomy is placed in a superb seat of marble, which was brought from Nismes more than 100 years ago. The library is only in its infancy. The botanic garden, which is the oldest in France, was instituted in 1598. There is also here a special school of pharmacy, and a well regulated hospital.

The old academy of sciences at Montpellier has been replaced by a literary society, called the Free Society of Sciences and Letters. There are also here a medical society, a society of practical medicine, and an agricultural society. An academy of arts, which distributes medals annually, was founded in 1781.

Montpellier contains several interesting cabinets, viz. that of the city, that of M. Lamoreux, which is very rich in rare shells; that of M. Marcel Serres, containing more than 9000 insects, and valuable minerals, and a considerable herbarium, belonging to M. Bouchet Doumeng.

The principal manufactures of Montpellier are those of brandy, perfumeries of all kinds, and verdigris, or acetate of copper. Corn, oil, silk, and wool, the productions of the neighbouring territory, are the principal sources of the commerce of Montpellier. Coverlets, handkerchiefs, and cotton cloths, are also manufactured here. These articles of trade are carried by the canal to Cette, which is the port of Montpellier.

The principal promenades of the city are, the Esplanade, the Peyrou, and the Canourgue. The Esplanade, begun in 1724, by the Duke de Roquelare, occupies the ground between the citadel and the ancient city. It is extensive, and shaded with rows of trees, and adorned with several large basins. The Place du Peyrou is situated on the highest part of Montpellier. The ground, supported by very high walls, forms two terraces, placed one above another. The lower one, which occupies the greatest space, is planted with several rows of trees, and adorned with two fine fountains. The wall of the upper terrace is surmounted with trophies. At the bottom of the place is the reservoir of water, which is supplied by the aqueduct, designed by M. Pitot, for conveying to Montpellier the waters of St. Clement. It has two rows of arcades, and the second supports a long gallery. This magnificent work is allowed to decay. The Canourgue is celebrated chiefly for being the place where Rousseau walked during his stay in that city. Population of Montpellier, 26,704. Its mean temperature is 59° 4′ of Fahrenheit. The observatory is situated in East Long. 3° 52′ 40″, and North Lat. 43° 36′ 15″. 47‴. For a full account of this town and its antiquities, see Millin's *Voyage dans les Departemens du Midi de la France*, tom. iv. chap. 114, 115, 116, p. 283.

MONTREAL, a town of North America, in Lower Canada, is situated on an island formed by the river Ottawas and the river St. Lawrence. The island is 32 miles long by 10 broad, and is very productive in all kinds of grain, vegetables, and fruits.

The town, which derives its name from a high mountain in the middle of the island, forms an oblong square, surrounded by a lofty but decaying wall. It is divided into the upper and the lower town. The old streets are narrow and gloomy, but the new ones are more open, extending parallel to the river, and crossed by others at right angles. Many of the houses are large and well built, of a greyish sort of stone, and in general are roofed with sheet iron or tin. The Place d'Armes, which is the only square, excepting the two market places, is situated on the side of the town farthest from the river, and was originally built for the purpose of military exercise. Montreal contains six churches, an Episcopalian, a Presbyterian, and four Roman Catholic churches. The cathedral church, which belongs to the Catholics, stands in the Place d'Armes. It is a spacious stone building, containing five richly decorated altars. The other public buildings and establishments are, the Hotel Dieu, for relieving the destitute sick, managed by a superior and 36 nuns; the convent of Notre Dame, for female instruction, managed by a superior and 60 nuns; the convent of the Grey Sisters and the Hospital of Invalids; the Seminary of St. Sulpice, for the education of youth; and the New College, which is a handsome building. The civil and criminal courts are held in a plain but neat building, in Notre Dame Street, and near it stands the jail, erected in a salubrious situation, on the site of the one which was burned down in 1803. The government house is an old and elegant building. The barracks, encircled with a lofty wall, and capable of containing 300 men, are agreeably situated near the river.

The harbour of Montreal is commodious: there are fifteen feet of water close to the shore, near the market-gate. Montreal is the great depot for the fur trade, of which we have already given some account in our articles CANADA and HUDSON'S BAY. The population of Montreal is stated, by Morse, to have been 16,000 in 1809, and by Gray to be 10,000, while others make it little more than 6000. For farther information respecting this place, see the works quoted under the article CANADA. West Long. 73° 35′, and North Lat. 45° 31′.

MONTROSE, a royal burgh, and maritime town in the county of Forfar, is situated at the mouth of the river South Esk, 70 miles north from Edinburgh, in 56° 34′ of north Latitude, and 2° 10′ of west Longitude from London. The ancient name of Montrose, according to Boece, was *Celurea*; but the etymology of its modern appellation has been variously resolved. In Latin, it is called *Manturum* by Ravenna; and by Cambden *Mons-rosarum*, "the Mount of Roses;" in French, *Mons-trois*, "the three hills or mounts;" in the ancient British, *Manter-rose*, "the mouth of the stream;" in the Gaelic, *Mon-ross*, "promontory-hill," or *Moin-ross*, "the promontory of the moss," or *meadh*, (pronounced *mu*) *an-ross*, "the field or plain of the peninsula." The second of these derivations, though the most unlikely of all, is countenanced by the seal of the town, which bears the ornament of roses, with the following motto, "Mare ditat, Rosa decorat;" but the two last, besides being the most probable, correspond best with the pronunciation of the name by the common people in the neighbourhood, and by all who speak the Gaelic language, viz. *Munross*.

The erection of Montrose into a royal burgh has generally been referred to the year 1352, the twenty-third of the reign of David II.; but there is every reason to think that the original charter must have emanated from David I. In the rolls of the parliament, which was held at Edinburgh, in September, 1357, for effecting the ransom of David II. from his captivity in England, the burgh of Montrose stands the ninth upon the list, with the names of eight other burghs behind it; a circumstance, which is scarcely compatible with the supposition of its having been created a royal burgh only five years before. It appears, at least, to have been a place of some note long before the earliest date assigned to its erection as a royal burgh; and is mentioned in Dalrymple's *Annals of Scotland*, among some of the principal cities of the kingdom which were nearly destroyed by fire in the year 1244. Its name is connected with many important events in Scottish history. It is mentioned by Froissart as the port from which Sir James Douglas embarked, in 1330, with a numerous and splendid retinue, on a pilgrimage to the holy land, carrying along with him the heart of Robert de Brus.* It is distinguished as the first place in Scotland where the Greek language was taught, by teachers from France, brought over by John Erskine of Dun, in 1534; and as having sent forth, from its seminary, the celebrated scholar Andrew Melville. It was the birth place of the warlike Marquis of Montrose; and the house in which he was born, was occupied as an inn not many years ago. It was the only town in Scotland, so late as the commencement of the eighteenth century, where a person could be found who understood the management of pumps in coal works, namely John Young, a citizen of Montrose, who had been sent over to Holland by the magistrates, for the purpose of learning the most improved modes of constructing and using windmills. It was the first port made by the French fleet, in December, 1715, with the Pretender on board; and that prince embarked at the same place in February of the following year. But one of the principal events of the history of Montrose regards an alteration in its own municipal constitution. The set of the burgh formerly consisted of nineteen members, seventeen as representatives of the guildry, and two as representing the seven incorporated trades. The old council elected the new; and the old and new elected the office-bearers. But the magistrates and council, upon the petition of the guild-brethren and the incorporated trades, granted to the former the election of their dean, who became *ex officio* a member of council; and to the latter the election of their two representatives in council; and this alteration in the set having been submitted to the convention of royal burghs for their approbation, was confirmed by them in July, 1816. In consequence, however, of an informality in the mode of electing the magistracy at Michaelmas following, the burgh was disfranchised by a sentence of the court of session; and, in answer to a petition from the inhabitants, a new charter, with an improved constitution, was granted by the crown, in the following terms: "That the town-council shall, as formerly, consist of nineteen persons, including in that number the provost, three bailies, the dean of guild, treasurer, and the master of the hospital; of which nineteen, fifteen shall be resident guild-brethren, and four shall be resident craftsmen, including the deacon-convener for the time: That, at the Michaelmas election, the six eldest councillors for the time from the guildry, who have not served in any of the offices after mentioned for the year preceding, and the whole four councillors from the craftsmen, shall go out, but shall nevertheless be re-eligible, if their respective constituents shall think fit: That, upon the Monday of the week immediately preceding Michaelmas, in each year, the magistrates and council shall meet, and declare the names of the six guild councillors who go out in rotation, and also what vacancies have arisen during the preceding years by death or otherwise, in the number of guild councillors: That, on the following day, being Tuesday, the guildry incorporation shall assemble at

* We have been indebted to James Burnes, Esq. the present provost of Montrose, for much curious information respecting the antiquities of the place, which we regret that our limits will not admit of our inserting at large.

their ordinary place of meeting, and shall first elect their dean of guild, and six members of the guildry, as his council for the ensuing year; and the person so chosen as dean of guild shall, in virtue of his office, be a magistrate and councillor of the burgh; and the said incorporation shall then proceed to fill up the vacancies in the number of merchant councillors, occasioned by rotation, non-acceptance, resignation, death, or otherwise, during the preceding year: That the seven incorporated trades shall also assemble together in one place on the said Tuesday, and shall first elect their deacon convener, who shall, in virtue of his office, be a councillor to represent the trades; and they shall then proceed to elect other three in the room of those who retire from office, and that two of the four trades-councillors to be so elected may be guild brethren, being always operative craftsmen, and the persons electing them shall have no vote in the guild in the same election; but the other two trades-councillors shall be operative craftsmen and burgesses only: That the council shall meet on the Wednesday immediately preceding Michaelmas, unless Michaelmas-day shall happen to be upon Wednesday, in which case they shall meet on Michaelmas-day, and conclude the annual election for the ensuing year, by continuing the *ex officiis* members, electing the two members of council, who do not go out by rotation, and receiving the new members from the guildry and trades; and, after such election, and receiving the new councillors, the members both of the old and new council shall, according to the formor set of the burgh, choose a provost, three bailies, a treasurer, and hospital-master; that the provost, bailies, treasurer, and hospital-master, shall not be continued in their offices longer than two years together; but they, with the dean of guild, shall remain *ex officiis* members of the council for the year immediately following that in which they shall have served in these offices respectively."

The town of Montrose stands on a level sandy plain, or peninsula, bounded on the north-east by the German Ocean, on the south by the river South Esk, and on the west by a large expanse of water, called the Basin, about eight miles in circumference. This basin, through which the South Esk flows into the sea, is nearly dry at low water; but is so completely filled by every tide, as to wash the garden walls on the west side of the town, and to afford sufficient depth of water in the channel of the river for allowing small sloops to be navigated to the distance of three miles above the harbour. At these periods of high water, the appearance of Montrose, when first discerned from the public road on the south, is peculiarly striking, and seldom fails to arrest the eye of a stranger: the basin opening towards the left in all the beauty of a circular lake; the fertile and fully cultivated fields rising gently from its banks; the numerous surrounding country-seats, which burst at once upon the view; the town, and harbour, and bay, stretching farther on the right; and the lofty summits of the Grampians, nearly in the centre of the landscape, closing the prospect towards the north-west—altogether present to the view of the traveller, one of the most magnificent and diversified amphitheatres to be found in the United Kingdoms. A handsome wooden bridge over the South Esk, (fully described in the Scots Magazine, Feb. 1817,) founded in 1793, about 700 feet in length, and one of the most remarkable structures of the kind in Great Britain, forms a fine approach to the town, with the harbour on the right, and the basin on the left. The river at this point is of considerable depth, about twenty feet at low water in ordinary tides, and thirty-five at spring tides; and so rapid, that it frequently runs at the rate of six miles an hour. On the west side of this entrance, and close upon the river, is the largest of the three mounts, to which the French name of the town is supposed to refer, called Forthill, on which a fortification was formerly erected, and in cutting through which, to form a new entrance to the town from the bridge, a stratum of human bones, nearly fourteen feet thick, was laid open. The harbour, on the east side of the bridge, is very commodious, and furnished with excellent quays. Two light-houses have been lately built, to direct vessels in taking the river during the night; and a large house, in which the keeper of the lights resides, is provided with accommodation for the recovery of persons who have suffered shipwreck. The spot upon which the town is built is nearly a dead flat, from which the sea appears to have gradually receded; but the soil, being a dry sandy beach, and the whole exposure completely open on every side, the climate is much more healthy than the lowness of the situation might give reason to expect. The town is neatly built, and consists chiefly of one spacious main street, from which numerous lanes run off on each side, as from the High Street of Edinburgh. Many of the houses have their gables turned to the street; but a number of more modern buildings are constructed in a different manner, and have a very handsome appearance. The principal public buildings are the *Town hall*, which has of late been greatly enlarged, and which makes a fine termination to the main street; the *Parish church*, which measures 98 feet by 65 over walls, a plain and well finished building, but awkwardly attached to an old and diminutive steeple; the *Episcopal chapel*, to the eastward of the town, neatly built and handsomely fitted up; the *Public schools*, in a safe and airy situation, and now almost entirely occupied by the English masters; the *Academy*, a spacious edifice, recently erected for the accommodation of the other teachers, and containing six large apartments, occupied by the master and usher of the Latin school, two masters for writing and arithmetic, a master for drawing, and a rector, whose department includes the different branches of mathematics, the elements of natural philosophy, and several of the modern languages; the *Lunatic asylum*, including also an infirmary and dispensary, founded in 1779, the first institution of the kind in Scotland, and which has been recently enlarged, and greatly improved in its whole appearance and arrangements; and the *Office of the British Linen Company's agents*, which forms one of the principal ornaments of the main street.

Montrose is a place of considerable commerce, and its shipping has, of late years, greatly increased. It is a port of the custom-house, and comprehends, within its bounds, the coast from the lights of Tay on the south, to Bervie-Brow, or the Todhead, on the north. In the month of March, 1820, the shipping belonging to Montrose amounted to 83 vessels, registered at 7046 tons, and navigated by 605 men. Five large vessels are employed in the whale fishery, but the greater part are engaged in the coasting and Baltic trade. The most important branch of the export trade is grain, which is said to exceed that of any other port in Scotland. Various branches of manufacturing industry are carried on in Montrose, particularly sail-cloth, sheeting and linen; the importance and progress of the last mentioned article of manufacture will appear from the following note of linen cloth stamped in the place.

	Yards.	Value. L. s. d.
From 1st Nov. 1815 to 1st Nov. 1816.	345,098¾	18,686 7 1¾
From . . 1816 to . . . 1817.	537,599½	27,405 6 10¼
From . . 1817 to . . . 1818.	513,410½	25,599 11 8
From . . 1818 to . . . 1819.	777,902	36,439 16 11

There is in the town an extensive tan-work and foundry; rope-walks, breweries, starch-works, soap and candle-works. There are excellent salmon-fishings in the river; most abundant supplies of fresh white fish from several fishing villages in the vicinity, and immense quantities of cod, particularly prepared by drying and salting, for distant markets. There are very extensive downs or links, between the town and the German Ocean, where the game of golf is generally played, and where races occasionally take place. There is a bank in Montrose, besides branches from the British Linen Company and the Dundee Union Bank. There are two newspapers, two printing offices, a theatre, lately erected, and an excellent public library, inststituted in 1785, which contains between five and six thousand volumes. Many genteel and wealthy families reside in the place. The inhabitants are distinguished for their intelligence and orderly habits. And, altogether, Montrose may be considered as one of the most interesting provincial towns of North Britain. The population is about 8000. (*q.*)

MONTSERRAT, one of the Leeward Caribbee Islands in the West Indies, was discovered in 1493 by Columbus, and was colonized in 1632 from the adventurers under Sir Thomas Warner. The island is of a circular form, and is about nine miles in diameter, containing about 30,000 acres of land, or nearly 47 square miles, of which about 6000 acres are laid out in sugar, 2000 in cotton, 2000 in provisions, 2000 in pasturage, the remaining two-thirds being mountainous. Cedars, cypresses, the iron-tree, and other woods and odoriferous shrubs, are produced on the island; and indigo was formerly raised in great quantities. From 1784 to 1788, the average crop was 2737 hhds. of sugar, of 1600 cwt.; 1107 puncheons of rum, and 275 bales of cotton. The following were the exports from Montserrat and Nevis in 1787, which were sent principally to Britain, the United States, the British colonies in America, and the West Indies:—

	cwt.	quart.	lbs.
Sugar, ...	111,284	0	21
Rum, ...	289,076	0	0 gallons.
Molasses	1,313	0	0 gallons.
Indigo, ...	140	0	0 lbs.
Cotton, ...	92,472	0	0 lbs.
Dyeing woods, valued at . .	352*l.*	7*s.*	6*d.*
Miscellaneous articles, valued at	1,363*l.*	3*s.*	5*d.*
Total value at the London market,	214,141*l.*	16*s.*	8*d.*

These articles were produced by the labour of about 1300 whites, and 10,000 negroes, which was the population of the island in 1791. In 1648 the white families were 1000, with a militia of 360 effective men.

In the year 1806, Montserrat imported the following articles of provision and lumber:—

	From Britain.	From United States.
Corn, . . .	6,230 bushels.	6,325 bushels
Bread, Flour, and Meal,	150 cwt.	19,555 cwt.
Beef and Pork, .	78 barrels.	416 barrels.
Dry Fish, ...		54 quint.
Pickled Fish, .	30 barrels.	632 barrels.
Butter, . .	19 firkins.	
Sheep and Hogs, ...		50 No.
Oak and Pine Boards . . .		395,908 feet.
Shingles, ...		597,000 No.
Staves, ...		117,600 No.

Montserrat is the most southern island under the governor general, and is 7 leagues SE. of Nevis, and 8 SW. of Antigua. West Long. 62° 13′ 25″ of NE. point, and North Lat. 16° 47′ 35″. See Edward's *History of the West Indies*, vol. i. and Gray's *Letters from Canada*.

MONTSERRAT, is the name of a mountain of Spain, in the province of Catalonia, celebrated for its hermitage, and as a place of resort for pilgrims. It is said to be about 24 miles in circumference, stretching from W. to E. along the right bank of the river Llobregat, and is equally remarkable for the composition, form, arrangement and position of its rocks. It consists of limestone, sand and pebbles, cemented together, and forming a kind of breccia. "The rich earth," says Laborde, "on part of these rocks being dissolved by the action of the rain water, has formed crevices full of trees and aromatic plants. This vegetation is the more extraordinary, as there is no spring on the mountain; the streamlets sometimes seen there appearing to proceed from reservoirs formed by rains in the crevices of the mountain, and running in the bed of porous stones, which lie across the middle of it." Hence the mountain seems to have been split into masses of the most grotesque shapes, in the form of caves, pillars, and rugged fragments, piled upon one another to the height of above 3000 feet above the level of the ocean. The view from the summit of Montserrat is extensive and grand. Corn, vines, and olives, cover the lower parts of the mountain. The situation of the highest peak of Montserrat is in East Long. 1° 46′ 7″, and North Lat. 41° 38′ 59″. See Laborde's *View of Spain*, vol. i. p. 125.

MONTUCLA, (Jean Etienne,) a French mathematician of considerable note, was born at Lyons, on the 5th of September, 1725. Being early distinguished for his love of knowledge, he was placed under the tuition of the Jesuits, from whom he gained the elements of an extensive acquaintance with science and classical literature. At the age of sixteen he quitted their seminary, for the purpose of studying law at Thoulouse, and, after the usual course of preparation, obtained a counsellorship in the Parliament of that city: but feeling little inclination for his employment, and meeting with little encouragement in the exercise of it, he renounced the bar in 1753, and removed to Paris, with the view of supporting himself by literary exertions. Soon after his arrival, being fortunately admitted to the society of d'Alembert and Diderot, their conversation gave a settled tendency to his pursuits, and he formed the project of that work, by which his name is so well known among men of science. At first, however, his efforts were limited to a lower department. He wrote in the *Gazette Françoise;* and translated several works, one of which was Lady Mary Wortley Montagu's report of the latest cases of inoculation at Constantinople. The utility of the practice at that time (1756,) about to be tried on a prince of the blood, was keenly discussed, and Montucla's translation appeared with advantage as an appendix to M. de la Condamine's memoir upon this question. Two years before, a subject more akin to the bent of his mind had furnished Montucla with scope for original investigation: it was the *Histoire des Recherches sur la Quadrature du Cercle*, received with an applause well calculated to animate the author in his great undertaking, the *Histoire des Mathématiques*.

Lord Bacon justly thought, that a rational account of the steps by which the mind had advanced to its actual proficiency, in the several departments of philosophy, might prove a work of great utility and entertainment. But though mathematical science is perhaps the only branch of human knowledge, which has attained the degree of accuracy and precision requisite for executing such an enterprize, the task of giving any thing like a regular narrative of the order and gradation, according to which the discoveries in that science had followed each other, seems to have been undertaken for the first time by M. de Montmort, the friend, and fellow-labourer of Bernoulli. M. de Montmort, however, did not live to complete his attempt; the materials which he had accumulated were entirely lost at his death, and Montucla had the undivided honour of supplying this desideratum. His work, in two volumes 4to, was published in 1758. The extensive acquaintance with the science, and the unwearied spirit of research which it displayed, were rewarded with universal applause; the defective arrangement, and the rather inelegant style, were forgotten in the general merits of the work, or excused, from the difficulty of treating so new and intricate a subject. In its first shape, the *Histoire des Mathématiques* extended only to the conclusion of the 17th century; but the author's diligence had not abated, and his promise of continuing the narrative to a later period was afterwards fulfilled.

In the meantime, however, his studies were impeded, though not suspended, by an appointment to the post of *Secretaire de l'Intendance* at Grenoble. His conduct in this office, which he held for three years, would seem to have given entire satisfaction, since, when M. Turgot was commissioned in 1764 to superintend the improvements which the government were endeavouring to introduce at Cayenne, Montucla was nominated to accompany him in the character of secretary, dignified also with the title of Astronomer Royal. Of Montucla's celestial observations we have no account, but the science of botany is indebted to him for the knowledge of several equinoctial plants brought home on his return, which happened in 1766. After this short absence, he became chief clerk to the overseers of the king's buildings. In the discharge of that easy duty, Montucla enjoyed a competence, and found leisure to prosecute his inquiries concerning his favourite subject. The stormy factions, which desolated France during the revolution, seem to have left him unharmed, till 1792, when his office was abolished by the republican government, and the historian of mathematics was left exposed in his old age to all the calamities of want. It is painful to relate, that the man, whose respectable character ought to have secured him esteem and patronage, even if his arduous labours in the cause of science had not benefited mankind, was unable to gain the necessaries of life, except by consigning those talents which had illustrated the highest achievements of our species, to the management of a lottery-office! It was not till within a few months of his death that a scanty pension of 100*l.* from the government raised him above the miseries of abject poverty. But, in the midst of these depressing circumstances, Montucla did not forget his promise to complete the history of mathematics. Forty years of application had greatly augmented his knowledge of the subject; the second edition of his work, begun in 1798, was enriched with many new details in the period before examined, and the relation might have been conducted with equal skill to the proposed termination, had not death put a stop to his exertions, on the 15th of December 1799. Happily his manuscripts were in such a state as to be capable of publication. The printing of the first part was continued without interruption; and M. de la Lande, in 1802, arranged the remaining papers into two additional volumes, which continue the history to the beginning of the 19th century. Montucla was a member of the Royal Academy of Sciences at Berlin, and of the French Institute, from its commencement. His manners are said to have been amiable, his disposition kindly and generous. The *Récréations Mathématiques et Physiques* of Ozanam, which he edited in 1778, is the only work connected with him that has been translated into English. (T. C.)

MOON. In the article ASTRONOMY, the reader will find the fullest information respecting this planet. The map of the moon, given in this work, and forming Plate CCCC. is engraven on a reduced scale from that which was drawn by Dr. Brewster, and published in his edition of *Ferguson's Astronomy*.

MOORE (DR. JOHN,) a noted miscellaneous writer, the son of Charles Moore, episcopal clergyman at Stirling, was born in the year 1730. Mrs. Moore, upon the death of her husband in 1735, having removed to Glasgow, where she possessed some property, John, her only surviving son, enjoyed the benefit of being educated in the Grammar school and College of that city. After obtaining a considerable acquaintance with classical literature, he was placed under the charge of Mr. Gordon, a practitioner in surgery; and at the same time attended the lectures of the medical professors in the university, among whom Dr. Cullen was already distinguished for his original ideas regarding the practice of physic.

The knowledge acquired from these teachers was not long in finding employment. By the kindness of the Duke of Argyle, Moore, in the 17th year of his age, was appointed mate to the military hospital established at Maestricht, during the war which Great Britain at that time carried on for the Empress Maria Theresa. He afterwards served in a similar capacity at Flushing; and next year he became assistant surgeon in the Coldstream guards, and passed the winter of 1748 under the command of General Braddock, afterwards so unhappily remarkable for his fate in North America.

The arrival of peace, which put a stop to Moore's advancement in the army, afforded him the opportunity of attending Dr. Hunter's course of Anatomy in London; and soon afterwards the Earl of Albemarle, our ambassador at the French court, to whom Moore had been introduced in Flanders, invited him to undertake the duties of Surgeon to his family at Paris. During the two years of his residence in that city, Moore diligently employed all the facilities which his situation afforded, to improve his medical knowledge; and so ardent was his desire of attaining this object, that he declined residing at the ambassador's house, in order to have more frequent opportunities of witnessing the practice at the hospitals, by living in the neighbourhood of those establishments. Constant application naturally increased his professional skill, and gave a favourable opinion of his assiduity; and Mr. Gordon was sufficiently impressed with the character and abilities of his former pupil, to propose admitting him to a share of his practice at Glasgow.

In partnership with this gentleman, and afterwards with Mr. Hamilton, professor of Anatomy, Moore enjoyed considerable success for a number of years. The University of Glasgow had honoured him with a degree; the cares and pleasures of a family were now added to his other engagements; and in the bosom of domestic comfort, his life seemed to give promise of being respectable and happy, but not distinguished by any thing superior to the lot of those around him; when, in 1769, an event occurred which imparted a new colour to his future pursuits. Among the patients who at this time came under his care, was James George, Duke of Hamilton; a young man possessed of talents and virtues, which were only prevented from doing honour to his exalted station, by the attack of a consumption that baffled all the arts of medicine, and cut him off in his fifteenth year. Dr. Moore's services, though ineffectual, were gratefully acknowledged by the family to whom they had been rendered. He wrote the epitaph, which records the fate and character of his patient, in Hamilton churchyard; and as the surviving brother of this nobleman was of a weakly constitution, his mother, for that reason, felt desirous that he should visit the continent in company with a person qualified at once to direct his observations, and watch over his health. Dr. Moore, in whom both these requisites were united, was prevailed on to accept the charge. He left Britain with his pupil in 1773, and spent five years in visiting the most remarkable countries of Europe.

The fruit of those travels, 'A View of Society and Manners in France, Switzerland, and Germany,' published at London in 1779, and followed, in 1781, by a similar account of Italy, procured the author some emolument, and a considerable literary reputation. These works were speedily translated into French, and read with applause by the people whom they professed to depict. They were read with equal applause in England, and are still deservedly admired for their spirited descriptions, their perpetual flow of lively, if not profound observation, and above all, for the vein of pungent, yet on the whole, good-natured humour, which lends a charm to their other merits.

It does not seem that Dr. Moore's efforts to obtain employment as a physician in the metropolis, whither his family had removed, soon after his return from abroad, were equally fortunate: and the reception of his 'Medical Sketches,' published in 1785, appears to have confirmed his predilection for the career of a man of letters. The success which the novel Zelucco met with, was not calculated to disappoint such hopes. Its strong delineations of character and passion, its scenes of pathos and pleasantry, redeemed the occasional harshness and exaggeration of this work, and gave to it a more lasting existence, than generally falls to the lot of similar productions.

The fame arising from these performances procured to Dr. Moore the advantages of a society fitted to appreciate his acquirements. He had corresponded with Dr. Smollett, and was prompt to encourage the genius of Robert Burns. His time seems chiefly to have been engaged by such intercourse, and by a limited exertion of his professional abilities, till, in 1792, the French revolution having awakened the attention of all Europe, Moore visited Paris in company with Lord Lauderdale, for the purpose of more narrowly inspecting a phenomenon so extraordinary and so vast. The 'Journal' of his residence in France, which he quitted immediately after the fatal 9th of September, was published on his return to England; and the author's ideas upon the object he had been contemplating, were given in a more mature shape under the title of 'Causes and Progress of the French Revolution,' three years afterwards. Though the temporary interest which caused these works to be eagerly sought after, at the time of their appearance, no longer exists, they still merit a perusal. The first, in particular, is noted for the fidelity and spirit with which it sketches some events that will long figure in the history of the world.

From politics Dr. Moore again turned his attention to novels. But his 'Edward' (1796,) and his 'Mordaunt' (1800,) added little to his literary character. Though they retain some traces of his early vigour, they both exhibit symptoms of exhaustion and decay. They were the last effort of his genius: he died at his house in Clifford-street, on the 20th Feb. 1802.

As an author, Dr. Moore was more distinguished by the range of his information, than by its accuracy or extent upon any particular subject; and his writings did not owe their celebrity to any great depth or even originality of thought. As a Novelist he shewed no extraordinary felicity in the department of invention; no great power of diversifying his characters, or ease in conducting his narrative. The main quality of his works is that particular species of Sardonic wit, with which they are indeed perhaps profusely tinctured, but which frequently confers a grace and poignancy on the general strain of good sense and judicious observation, that pervades the whole of them. (T. C.)

MOORE, (Sir John,) a son of Dr. Moore, the subject of our preceding article, was born at Glasgow, on the 13th of November, 1761. Being destined for the military profession, he was educated chiefly on the continent; and whilst his father was abroad with the Duke of Hamilton, the interest of that nobleman procured him admission to the service, in the capacity of ensign to the 51st regiment of foot. It was at Minorca, in 1776, that Moore first entered the army; a lieutenancy in the 82d regiment was the next step of his promotion, and he seems to have held this station without much distinction, or any censure, during the several campaigns of the American war, in which he served till the arrival of peace, when his regiment was reduced in 1783.

A seat in the Parliament, as member for Lanark and the adjoining burghs, obtained apparently by the influence of the patron above referred to, did not long interrupt his advancement. About the year 1788, the office of major in the 4th battalion of the 60th regiment of foot, was exchanged for a similar post in his original regiment, the 51st, and followed by the commission of lieutenant colonel, which he purchased in that corps two years afterwards. From Gibraltar, where his military duties had placed him, he was ordered to Corsica in 1794; and the esteem of General Charles Stuart, formed an epoch in his military life. The siege of Calvi was the scene of this distinction; and his first wound was received in storming tbe Mozzello fort.

When a disagreement with the Viceroy had produced the recal of General Stuart, Moore succeeded him in the character of Adjutant-General; but as the subject of dispute with the Viceroy still subsisted, the new commander remained not long in good terms with him. His return to England, in the year 1795, seems not to have proceeded from dissatisfaction on the part of government; and his appointment to the rank of Brigadier General in the West Indies, which followed immediately, opened a new and more conspicuous field to his military talents. At Barbadoes, in consequence of his appointment, he met Sir Ralph Abercrombie, commander of the expedition destined to act against St. Lucie; and in this hazardous service, of which an important department was assigned to General Moore, he acquitted himself with that steadiness and gallantry which excited the warm applause of his superior officer. The conqueror of St. Lucie, who had already designated General Moore as "the admiration of the whole army," committed to him the prosecution of his enterprise, together with the government of the Island; and this charge, undertaken with reluctance, and rendered full of danger and labour from the hostility of the natives, and the number of Maroon negroes, who constantly infested the country, was managed with a decision and activity that overcame every obstacle.

Two successive attacks of the yellow fever soon forced General Moore to leave the West Indies; but, in company with Sir Ralph Abercrombie, he was destined to earn still higher distinction. The first scene in which they again acted together, was the Irish rebellion; and during those unhappy contests, notwithstanding the disorganised state of the army, General Moore's conduct was such as to obtain universal approbation.

After Sir Ralph's expedition to Holland, (1799,) in which General Moore was severely wounded, a wider and more briliant theatre was soon afterwards presented for their united exertions in the expedition to Egypt. During this celebrated campaign, General Moore fully supported the reputation for bravery and coolness which his former services had acquired. An important charge in disembarking the troops was assigned to him; and the battalion which he led was among the foremost in the far-famed enterprise of storming the French batteries, erected on a neighbouring eminence of sand, to oppose their landing. His subsequent efforts ably seconded the commander's arrangements, and contributed materially to the happy issue of their undertaking. That victory, which was purchased with the life of Sir Ralph Abercrombie, disabled General Moore for a time from farther exertion; a dangerous wound in his leg confined him first on board one of the transports, and afterwards in the neighbourhood of Rosetta, till the conclusion of the expedition. His merits were rewarded, on his return to England, by the order of knighthood; and public opinion seemed to point him out as a fit person for conducting any military operation in which the country might require his services.

The period for verifying those ideas was not long in arriving. After a few years of repose, General Moore (1808) was called to take upon him the command of an armament which the British government had prepared in aid of the Spanish Patriots, now engaged in hostilities with Napoleon. It is not our business to relate the particulars of this expedition. It is enough to observe, that after an advance to Salamanca, in which he was chagrined by every species of disappointment, cramped by restrictions, perplexed by misinformation, and, after a fruitless attempt to penetrate into Portugal, General Moore commenced a retreat to the coast, conducted it successfully in the face of an enemy greatly superior, and by his masterly dispositions at Corunna, repelled the formidable attack, in which a cannon-ball deprived him of life,—though not till his last moments were consoled by intelligence that victory had secured a safe embarkation for his troops. He died with the equanimity which became him, on the 16th of January, 1809.

Succeeding achievements of a more extensive and important nature, have already eclipsed Sir John Moore's reputation. But the intrepidity and manly uprightness of his character, manifested at a time when the British army was far from being distinguished in these respects, are qualities more endearing and estimable than military fame. They extorted admiration even from his enemies; and the monument erected by the French officers over his grave at Corunna, attests the worth of both parties. (T. C.)

MORAL PHILOSOPHY.

Moral Philosophy is the science which treats of the motives and the rules of human actions; and of the ends to which they ought to be directed.

In contemplating the general history of animated nature, we make no hesitation in setting down the habits of an individual as characteristics of the species, on the grounds that creatures similarly constituted, possessed of the same organs, and impelled by the same instincts, must have the same dispositions and feelings. The human race presents a remarkable exception to this observation; and the varieties which it exhibits in external appearance are not half so numerous or striking, as the contrasts which we observe in moral conduct and feeling.

Were mankind placed in circumstances precisely similar; were they possessed of the same extent of mental powers, and the same degree of natural feeling,—we could scarcely conceive a diversity of sentiment or conduct to be possible. But when we consider the infinite variety which prevails in the external circumstances, and undoubtedly also in the mental powers of man, instead of wondering at the contrariety of views and feelings, we have greater reason to be surprised at their general harmony and agreement. The differences seem to be only accidental; and, even where they are most apparent, a principle of congruity may generally be discerned, which leads to the same end, though by the employment of different means; and brings the most anomalous appearances within the ordinary range of human feelings.

There must, then, be some strong leading principles in the constitution of man, or in the ordinary arrangements of Providence, to preserve order amidst such discordant materials, which, in many instances, seem directed not only against the comfort, but against the very existence of society.

——— Vix nunc obsistur illis
Quia lanient mundum.

According to some, this object is accomplished by the continual interference of Providence, to rectify the disorders which the passions of men have produced. We are not much inclined to object to this doctrine. We would receive it with this qualification, however, that a wise arrangement, continually upheld by the Being who first contrived it, is to be considered as a direct display of divine providence. But, admitting this, we contend, at the same time, that a provision is made, in the nature of things, (not from any necessity of nature, but by the will of the author of nature,) for maintaining the equilibrium of the moral world, and for restraining the vices, as well as influencing the feelings and the conduct of men.

It cannot be a random principle which produces such uniform results; nor can it be a very abstruse one, since its influence is universal, and is felt, with various degrees of force, in every stage of human society. But though the general complexion of human manners bespeaks the operation of a principle common to human nature, there is nothing with regard to which men are less agreed, than the name and nature of that principle which produces such extensive effects. Men differ both as to the object which constitutes the supreme good, or chief felicity of their nature, and also as to the means by which it is most likely to be secured. They do not sufficiently distinguish between the principles which impel to action, and the objects to which they look for gratification. They are both indiscriminately called motives; and, certainly, when any object acquires paramount importance in the imagination, it operates as a motive in regulating the whole conduct. It is, however, in all probability, only a confirmed prejudice, arising out of a perversion of the original impelling principle, which is merely a vague appetency of our nature, calling for gratification, but not directing us, with infallible certainty, to a specific object, nor to the mode and measure in which it ought to be enjoyed. There is another thing, therefore, to be attended to in moral discussions, besides our elementary feelings; for, after adopting the instincts, desires, and passions, implanted in our nature, as the elements of action, we must examine how far these principles have been legitimately exercised, and consider in what instances they have been carried too far, or have fallen short of what they might have fairly achieved.

In investigating the principles of moral conduct, then, the natural method is, to begin with the simplest elements of feeling: and then to proceed to the circumstances which occur in the constitution of our bodies, or in the powers of our minds, or in the order of external nature, to modify, limit, and restrain our appetites and feelings: and if this process is conducted judiciously, we shall probably find, that the Author of our nature has established immutable rules in the ordinations of his providence, to lead us to the high purposes for which we are destined.

If we shall succeed in establishing this point, it will prove incontrovertibly that there is nothing arbitrary or conventional in morals; but that they result necessarily from the powers and faculties which God has given to man, and from the circumstances in which he has placed him. Even the most exalted moral precepts, derived from the light of revelation, will be found not to controvert, but to confirm this position. It is a great mistake to suppose that Christianity unfolds moral precepts foreign to the nature of man, and not cognizable by his reason. It is addressed to him as a perverted being, not as one destitute of the materials of knowledge: it shows that he neglects the riches which are among his hands, and that he fails to deduce the inferences which are obviously presented in his own nature, in the constitution of the external world, and in the ordinary events of providence. It is doing Christianity great injustice, to suppose that its moral precepts are such as never did or could enter the mind of man without it. Grotius takes up a very different argument to prove the divine origin of the Christian religion; for he endeavours to show that it was so reasonable, and so admirably adapted to the nature and circumstances of man, that all its precepts might be recognized in the scattered maxims diffused among the human race; but in all cases deformed by impure admixtures, and perverted from their original purpose by the vices and passions of men. The grand object of Christianity was, to unfold a plan of mercy, which must otherwise have remained unknown: its peculiarity, as a moral system, consists in the powerful sanctions by which its simple and obvious precepts are enforced. Instead, then, of being jealous of those moral maxims adopted, and beautifully illustrated, by many heathen authors, every Christian should consider them as so many attestations to the existence of that immutable law on which God has laid the foundation of morals. To deny the existence of such a law, would be to destroy at once the moral responsibility of man, where the light of revelation is unknown; for "where there is no law there is no transgression,"—an assertion which the apostle makes, not to free the unenlightened heathen from responsibility, but to show their great guilt in neglecting the clear intimations written on their hearts, and pointed out by the general constitution and course of nature. But unless such intimations existed, no blame could attach; for who could be censured for invincible ignorance?

The law of moral action is in fact so irrevocably fixed, that even when we violate it unconsciously, we are corrected, and called back to the consideration of the circumstances which have affected our comfort. Thus temperance, one of the cardinal virtues, is forced on us by necessity; and whenever we go beyond the limits prescribed by the constitution of our nature, we are instantly punished, and taught to seek that just medium which may satisfy, but not satiate; and exhilarate, without subverting by excessive excitement.

But although it is quite evident that the Author of our existence has put into our hands the materials of knowledge, and directed us, by the constitution and circumstances of our nature, to the course of moral action which we should pursue; yet it is certain that we never could convert these materials to our advantage, without the aid of information superior to that afforded by the natural reason of man. All that we have hitherto said amounts merely to this, that God has most abundantly furnished the means of information, with regard to the leading duties of morality: and we must now farther admit, that the materials of prejudice and error are no less abundantly supplied by the tendency of our appetites and passions. It is this which renders human nature a strange medley of folly and of wisdom; of virtuous feelings and depraved affections; which weakens the convictions even of the most enlightened, and teaches them to desire an authoritative rule and sanction, for the regulation of their conduct.—In short, the principles of natural morality stand pretty nearly on the same footing with the principles of natural religion: for though the being and attributes of God may be inferred from all his works, yet we see that the natural reason of man never led him to just and accurate conceptions on the subject. In the same manner, though the rule of moral conduct may be traced in the order of nature, and in the constitution of our own minds, yet there can be no doubt that the light of revelation was necessary, to enable mankind to distinguish, with certainty, truth from error, and the illusions of the passions from the rule of right reason. For who could decide with absolute certainty amidst the endless varieties of human opinions; or expect to have the authority of an oracle in commanding the assent of mankind?

This difficulty was so powerfully felt by Socrates, that he deemed it necessary that an instructor should be sent from heaven with special authority to reveal and enforce the duty of man. Cicero did not go quite so far as this; but his words evince no less clearly the necessity of such a teacher. He says, that he was not one of those who maintained that there was no such thing as absolute truth; but that error was so mixed up with every truth, that it could not be accurately distinguished.* And to prove the truth of this observation, he adduces the discordant opinions of the principal philosophical sects respecting the nature of the gods. If we are more fortunate than those two illustrious heathens, and can proceed with greater confidence in our investigations, it is because we have been favoured with a revelation which was denied to them, and which has materially influenced the moral discussions even of those who reject its assistance.

In our researches we do not mean to set reason and revelation in opposition to each other, but to exhibit them as mutually co-operating to establish the same important results. It is the proper province of theology to enforce the sanctions of revealed religion: it is the business of our present department to analyse the principles of moral action, and to point out their foundation in the nature and circumstances of man.—It is not indeed possible, in any discussion on the subject, to separate morals wholly from theology. For as soon as men have acquired a belief in the existence of a God, their moral perceptions must be considerably influenced by the attributes which they assign to him. If he is supposed to be cruel, or vindictive, or lascivious, we may naturally expect to see the same qualities exemplified in the character of his votaries; for wherever men have admitted the existence of a God, they have also admitted that they were bound both to imitate and obey him.—It is absolutely necessary, then, in all moral discussion, to endeavour to ascertain how far the unaided powers of man can go in obtaining right conceptions of the divine nature and attributes; for if these could be properly ascertained, they would constitute a rule from which there could be no appeal.

This point will be soon settled, if we take facts for the foundation of our argument, and consider what has actually been done in the province of natural theology by the unassisted efforts of the human understanding. We have only to recollect the impure and absurd theology of the Romans, Greeks, and Egyptians; which some writers have chosen to denominate *elegant*, merely because its absurdities have been concealed under the splendour of poetical diction and imagery: or we have only to read Cicero's book on the *nature of the gods*, and if facts may be allowed to influence our reasoning, we will not hesitate to pronounce at once the incompetency of human reason to discover the attributes and perfections of the Supreme Being.

It may, perhaps, be thought unfair to decide on the capabilities of the human mind, from its aberrations and perversions; and we may be called upon to contemplate what it is naturally able to achieve. But here our speculations must be involved in great uncertainty. We find, indeed, the belief in a Supreme Being to be almost universal. In many instances, we discover very enlightened views respecting the unity of his nature, and some of his attributes; but in no one case can we pronounce with certainty how far these notions are the product of unassisted reason. We have stated elsewhere, (see Logic,) the very natural process by which the idea of God may be supposed to arise in the human mind; but it is impossible to demonstrate that it ever has arisen, in any one instance, in this manner. We are firmly persuaded that there is no such thing in the universe as a system of theism, the pure result of human reason; for it will not be difficult to show that all the religions which have ever been in the world are either *traditional* or *revealed*.

As far as we are acquainted with the religious systems which prevail throughout the immense continent of Asia, from China to the Red Sea, and from Cape Comorin to Siberia, we may discover the traces of a *traditional superstition*, but not of a system of *natural religion;* for its features are too fantastic to pass as the offspring of reason. In the same manner, we may perceive that the religions of Greece, of Rome, of Egypt, and of India, had a common origin, not in reason, but in tradition; for reason is not so uniform in its aberrations, as to run into exactly the same conceits and absurdities.

Where, then, shall we discover the pure religion of nature? Not among the sages of Greece and Rome: they evidently and avowedly borrowed from more ancient sources. Not among the philosophers and hierophants of Egypt: they, in all probability, borrowed from India. Nowhere, indeed, do we find among any of these nations any pretensions to this religion of nature: they altogether disavow this origin of their religious opinions; for they have, severally, their legislators and their sages, to whom they ascribe the origin of their laws and of their religion; and however much they may be disposed to reverence these founders of their polities, civil and sacred, they never ascribe to them the honour of discovering, by their own ingenuity, the laws and religious opinions which they promulgated. These they ascribe to the particular favour and illumination of the gods.

This opinion, if not strictly correct, may, perhaps, lead us to the truth; for were we to judge from appearances and partial facts, we would perhaps be led to conclude, that man, on his creation, was placed under a system of revelation, or was made perfectly acquainted with the great truths of religion, immediately depending on the being and attributes of God. This inference amounts to certainty, if we take the sacred Scriptures for our guide. On the supposition, then, (and it is surely a natural one,) that this primeval religion was taught by the first race of men to their families and descendants, and by this means diffused over the face of the earth, we might na-

* Non enim sumus ii, quibus nihil verum esse videatur; sed ii, qui omnibus veris falsa quædam adjuncta esse dicamus, tanta similitudine, ut in iis nulla insit certa judicandi et adsentiendi nota.—*De Nat. Deor.* lib. i. c. 5.

turally expect those diversified features of superstition, which meet us in our researches, and which betray few marks of their parentage as the offspring of reason, but are exactly what we might expect as the corrupted traditions of primeval revelation.

If, however, it should be maintained, that the due exercise of reason will necessarily lead us to some knowledge of God, we have no wish to dispute the assertion: we only affirm that we have no instance on record, in which it can be proved that men have come by their religion in this manner: all the religions with which we are acquainted, bear evident marks of a different origin: and before the competency of human reason, to discover the most obvious truths of religion, can be ascertained, it would be necessary to find a nation entirely destitute of every notion of religion; to watch its progress in knowledge, and carefully to observe the result of its experience. But, indeed, there is every probability that a nation, circumstanced as we have supposed, if unaffected by any external impulse, and unassisted by extraneous example, would remain for ever in the barbarism in which it was found. No nation, however, has been found in this state of absolute ignorance; by whatever means men have come by their knowledge, they have always been found to have some idea of a superior power; and, possessing this as the rudiments of religious knowledge, we might naturally have expected that they would have made progress in a science so interesting. This expectation will not be realized; for we discover none of that elasticity of mind, which prompts to ulterior improvement in religious knowledge: all the efforts of philanthropy have scarcely been able to shake the inveterate prejudices of error, or to preserve alive the seeds of knowledge, where they have been sown. If the knowledge of God and his attributes, then, be the result of human reason, the mind goes through a process on this subject, entirely different from that which it follows with regard to any other of its attainments. It advances uniformly and steadily in all those improvements which result from study or experience, and length of time never fails to give maturity and stability to the principles of knowledge. But, in religion, the process is reversed; and lapse of time invariably leads to degeneracy and corruption. The most ancient writings of the human race approach nearest to the truth on some of the fundamental principles of religion. Thus, we find the unity of the divine nature explicitly stated in some of the most ancient of the Braminical writings, whilst the doctrine is totally unknown among the modern Hindoos, who are, and have been from time immemorial, the grossest idolaters in the world.

Let it be remembered, that we are only stating the aberrations of human reason on the grand fundamental principles of religion and morals; and we do not positively affirm that the mind is absolutely incompetent to discover the important truth of the being of God; but facts authorize us to conclude that it never could turn this important truth to any profitable account, without ulterior assistance; for it is instantly disfigured by the prejudices arising from human passions, and thus becomes the means of perversion rather than of improvement; as men canonize their own vices by exalting them into attributes of their gods.

We conceive it, then, to be absolutely impossible to found a system of morals on the basis of natural religion, which, if cognizable by human reason, is nevertheless, in every instance, so grossly abused as to become a source of error rather than of knowledge. The bountiful author of our nature has delivered us from this perplexity, by giving us a revelation containing rules of duty, which our consciences must instantly approve, and which, on examination, are found to be perfectly consistent with the light of reason, with the interests of man, and with the ordinary arrangements of providence. These rules, however, are not, in general practice, deduced step by step from the elements into which they may be analysed: they resemble, in this respect, the rules deduced from science, or experience, which are delivered to practical artists, and which lead them as immediately to the attainment of their object, as if they thoroughly understood the principles on which the rules were founded. It is evident that some rule of this kind is absolutely necessary for regulating the moral conduct of men; for few have time or talents for ingenious or laborious investigations; and were man left to discover the rules by which his conduct is to be guided, the best of his life would be past before he had learned how to live. Revelation unfolds the rule at once, without explaining the principles on which it is founded, farther than by assuring us that it is the will of God, who always consults our happiness. To analyse these rules, however, which have been beneficently revealed for the regulation of our conduct, and to discover their coincidence with the most obvious principles presented to the senses and reason of man, is a luxury reserved for those whose talents and education enable them to trace the chain of proximate causes, till they can connect it with the supreme lawgiver.

It might reasonably be supposed that the will of God, and the order of nature, would tend mutually to illustrate and explain each other. This must necessarily happen, provided that which is communicated as the will of God be indeed from heaven; for the same God who arranged the order of nature, cannot, consistently with any notions which we entertain of his perfections, give a revelation which contradicts it.

"Nunquam aliud natura, aliud sapientia dixit."

This argument has been carried by Hume to an unwarrantable and unphilosophical extreme in the case of miracles, which are a suspension, or contravention, of the ordinary laws of nature. Were miracles contrary not only to the established laws of nature, but to the known power and perfections of God, it would be impossible to believe them. But when we see that they are not inconsistent with divine power, since he who gave matter its properties, can as easily alter them; when we see that they are obviously useful in promoting some beneficent end, which could not be accomplished without them; and when, in addition to all this, we have a positive proof in the existing state of nature, that a miracle *must* have been performed before things were as they are; (for if the calling of light out of darkness, of order out of confusion, of substance out of nonentity, be not a miracle, we do not know what is—or if any one should insist that there never was any creation, but that all things have always existed as we see them, that man holds a creed more marvellous than any miracle;) taking all these considerations together, there can be no objection to miracles in the nature of things, and their credibility, in every instance, must depend on the evidence by which they are attested.

The will of God, where it is known, must always be the rule of conduct. Let it but be fairly established that a precept has proceeded from heaven, and it would be needless to argue where it would be impious to resist. But there are a great many cases to which this determinate rule cannot be directly applied. Even the revealed law of God does not afford a direct rule for the moral conduct of man, in many instances where it is of essential consequence that he should decide with prudence. He is, therefore, under the necessity of employing his reasoning faculties in order to connect the case which puzzles him, with some general principle, or to trace its alliance with some recognised law.

At first view, it might appear desirable, that no doubt should ever exist on a moral question; and that we should be instantly enabled to decide with certainty in every case, where we are called to appear as moral agents. But this is not the way in which the author of our nature trains us to knowledge and to virtue. Our intellectual faculties are sharpened by the necessity imposed upon us of unravelling the studied involutions of nature. Some connecting principle is always presented to us as a clue to direct our steps, or some analogous fact occurs as an illustration: and before we reach the object which we have in view, we are generally raised above it; having travelled through a labyrinth of knowledge, whose hidden treasures we have been compelled to explore. By this means we perceive that the truth which, in the outset, we proposed as the ultimate object of our researches, is only a link in the chain of causes which connect matter with its creator. Something similar occurs in moral investigations. A doubtful point is cleared up by tracing its connection with others more fully established, or with acknowledged axioms in the constitution of our nature; and we are thus led to the temple of truth through a path beautifully diversified, which affords pleasure and instruction at every step, and beguiles the tediousness of the way by the many interesting objects which are successively presented to our view.

Thus, the same law, which, in physics, leads us to general principles from individual facts, might, by a careful process of moral generalization, conduct to results no less certain, could we disentangle our reason from our passions, and subject our feelings to our judgment. Ample materials are furnished to assist us in these researches: and as moral truths are infinitely more important than any physical results, the beneficent author of our being has afforded more numerous helps to conduct us to conclusions so essential to our happiness. Instinct, reason, judgment, conscience, point to the same goal; and though they are all sometimes so bewildered as to miss the right road, yet they possess in themselves a principle of rectification, which both points out their error, and incites to fresh attempts to discover truth, happiness, and duty.

Besides the intimations which spring up within our own breasts, and which are confirmed by the general habitudes of human nature, we may learn lessons of morality from the instincts of the lower animals; and the constancy, fidelity, gratitude, and parental affection, which, in many instances, they display in such an eminent degree, cannot fail to strengthen our moral perceptions. Many beautiful illustrations in the sacred Scriptures are founded on this idea; and we are frequently exhorted to draw moral and religious instructions from the instincts and habits of the lower animals. "*Go to the ant, thou sluggard, consider her ways, and be wise;*" we are here directed to an excellent example of industry and foresight. "*Consider the fowls of the air, for they sow not, neither do they reap, nor gather into barns, yet your heavenly father feedeth them; are not ye much better than they?*" These plain facts afford an excellent argument for trust in Divine providence.

Nor is this all: our moral feelings are, to a certain extent, regulated by the physical constitution of our bodies, and by the circumstances in which we are placed; and whenever we fall into extremes, either of deficiency or of excess, we find monitors within and around us, to stimulate our languid affections, or to repress our headlong desires.

Although all these intimations of duty, which are so profusely scattered around, would in themselves be insufficient to afford a universally applicable rule of duty; (because our prejudices disqualify us from drawing sound and accurate conclusions;) yet they are powerful auxiliaries in moral reasoning, and afford essential aid even where conviction is produced by other means. A moral precept, confirmed by miracles, may, nevertheless, be contrary to our limited views, or depraved affections: in that case, we are compelled, rather than inclined, to submit. But let it be shown that the precept in question is exactly conformable in spirit, design, and circumstances, to what we observe and approve in other cases, and then all opposition must appear unreasonable, and we must stand condemned by our own mouths, and our own consciences. In fact, it is not demonstration that we so much stand in need of in moral reasoning, as persuasion. The grand truths of morality are sufficiently palpable to command the conviction of the conscience and reason; but something more is necessary to give them a firm hold on our feelings. In subjects of pure science, where nothing but reason is concerned, nothing but reason requires to be satisfied; and a demonstration silences for ever all doubts and conjectures. But the case is wholly different in morals and religion: these sciences are intimately blended with our feelings: and when they inculcate disagreeable truths, or unwelcome precepts, our passions and prejudices will, most probably, be up in arms to resist the convictions of reason.

In all investigations, then, into subjects of morality and religion, it is not enough that our own reason be satisfied; the point to be enforced must be made familiar to our senses; must be reconciled to our prejudices, and shown to be consistent with those notions which we are compelled to admit as primary and incontrovertible facts. Hence, we find, in general, that illustrations in moral subjects are more effectual than reasoning; and familiar views, drawn from an induction of obvious facts, are more satisfactory than the most elaborate abstract speculations.

In another part of this work, (See Logic,) we have shown how much our intellectual perceptions are influenced by the order and course of nature; and that those mental features which appear most singular, are impressed on the mind by that invariable order, which the Almighty has established among his works. This regular order both facilitates the acquisition of knowledge, and, by its frequent occurrence, stamps it, in indelible characters, on the human mind. The same observation applies to our moral feelings. The law of God is, indeed, the ultimate rule; but that law is written, to a certain degree, on our own hearts, because the very instincts which he has given us compel us to observe it; and our experience soon teaches us, that we never can infringe, with impunity, those rules which are indicated by the constitution of nature. God has written his law, not only on our hearts, but on the face of nature; and his revealed law is only the enforcement and illustration of principles which were always in operation, and might always have been discovered, had not the sins of man enfeebled and obscured his reason*.

Next to the revealed law of God, then, we would be disposed to say, that nature is our surest guide; we do not mean merely the feelings of human nature, which are evidently under a corrupting influence, but the nature of things, that is, the arrangements of providence, and the constitution of the external world. These are the aids which the Almighty has given to direct us to the knowledge of his will, and to strengthen that revelation which our ignorance rendered necessary. We conceive that this representation is confirmed by Scripture. At the very time that God was giving a positive revelation to Israel, he appealed to their own interest, and told them that the law which he ordained was for their own good. Deut. vi. 24.

And farther, that he might not seem to impose strange and arbitrary precepts, having no foundation but in his own despotic will, he told them, that the law which they were commanded to observe was perfectly conformable to the intimations of their conscience and reason. *This commandment, which I command thee this day, is not hidden from thee, neither is it far off:—but the word is very nigh unto thee, in thy mouth, and in thy heart, that thou mayest do it.*

Our intellectual and moral faculties, though most closely allied, admit nevertheless of an obvious distinction. It is the province of the intellectual faculties to receive impressions, to perceive relations, to examine our attainments, and to see if they have been legitimately acquired: and if it shall be found that we have viewed things as they are actually presented in nature, and have combined them according to those analogies and relations which the author of nature has established, we have nearly exhausted the philosophy of the human mind. The moral faculties have a farther, and most important office to perform: for it is their province to decide how far the things which are presented to our senses, or suggested to our feelings, are conducive to the general happiness of our nature, and to what extent we may enjoy them consistently with our duty as moral agents. Those original impulses of our nature, or those desires and feelings of want which are born with us, put in motion the intellectual machinery of the human mind; they direct it to certain objects of gratification; and when these are obtained, it is a matter of feeling to decide on the degree of enjoyment which has been received. If, instead of enjoyment, the result has been pain, we are forced to conclude, that the object which has produced this effect, is not intended for gratification; or that we have not applied it aright for the purposes of enjoyment.

We are thus impelled to fresh pursuits, and when, at last, we discover that, which yields the desired enjoyment to ourselves, without impairing the happiness of others, and which is approved by our reason, whilst it gratifies our feelings, we conclude that we have found the right medium prescribed by the author of our existence. These experiments may go a considerable length in ascertaining the rule of moral conduct; for we are not left to grope at random; nature and conscience are always at hand to direct or to restrain us; and we are surrounded, from our very birth, by moral relations, which train and discipline our minds, involuntarily and unconsciously, to the habits and duties of moral agents.

But here we must observe, that those circumstances which constitute the rule of moral action do not, by any means, necessarily give us the idea of moral obligation. We can easily perceive, that we cannot exceed certain limits without destroying our own happiness; a regard to our own comfort, therefore, will compel us to respect those boundaries which nature has prescribed, as necessary to preserve us from the excesses which ruin our respectability or enjoyments. But there is no more virtue in this than there is in avoiding the fire which has burned us, or the food which has impaired our health, or the person who has injured or betrayed us. We are merely obeying a law which we dare not violate, from apprehension of the consequences; and which has the force of a statutory enactment, to secure the submission even of those who may dislike the injunction. We cannot conceive how it is possible that there should be any idea of moral obligation, without the idea of accountableness to that Being who created the universe; who implanted in our nature those faculties which enable us to act, and to judge; and who has established that order of nature which we are compelled to respect. Take away the conviction of this accountableness, and there is no distinction between virtue and vice; and nothing is left but a sordid calculation of the consequences which may affect our present comfort. A man's visible interest would then be his only rule, and there would be none of those high-toned principles, which make the *nil conscire sibi* the proudest distinction of human nature: the object would then be, to preserve a good name rather than a clear conscience; the most profligate would be sensible of no baseness; and the most abandoned wretch would lift his head erect, so long as he could conceal his turpitude from the world.

In order, then, to obtain a moral principle of sufficient efficacy, man must consider himself as amenable to the laws of the Supreme Governor; and he must seek to know his will by all the means by which he has been pleased to make it known to men: he ought gratefully to avail himself of the light of revelation, and he ought not to disregard those intimations which are presented in the order and course of nature; he ought to consider them as so many auxiliary hints to strengthen the obligations of virtue; and even as useful to ascertain many points of importance, which are not settled by a positive rule, but may easily be reduced to a general law.

Holding these views, we cannot subscribe to the opinions of Butler, and Mr. Stewart, (who is very much influenced by him,) that nothing farther is necessary to show the obligation of the law of morals than the bare recognition of its existence. "Your obligation to obey this law," says Butler, "is its being the law of your nature." But, according to the usual conceptions of men, wherever there is a law, there is a lawgiver; and it is

* Proinde sic statuimus nihilominus divina precepta esse ea, quæ a sensu communi et naturæ judicio mutuati docti homines gentiles literis mandarunt, quam quæ extant in ipsis saxeis Mosis tabulis. Neque ille ipse celestis pater pluris a nobis fieri eas leges voluit, quas in saxis scripsit, quam quas in ipsos animorum nostrorum sensus impresserit. *Melancthon.*

not the law itself, but the power and authority of the lawgiver, which enforce its obligations. Allowing, then, that the law of our nature were ever so clearly recognized, it could not be viewed as an object of moral approbation, were we persuaded that it was the result of fate, or of accident. It is only as proceeding from an intelligent cause, and from a being who has willed and planned our happiness, that we can admire and love the law under which we act; for it is then only that we consider it as an intimation of the will of a being who is the sovereign arbiter of our fate, and who will undoubtedly, some time or other, give full efficacy to the laws which he has established.

"Every being," says Mr. Stewart, "who is conscious of the distinction between right and wrong, carries about with him a law which he is bound to observe; notwithstanding he may be in total ignorance of a future state." This is the same idea as Butler's; and we apprehend it brings consequences after it which neither of these writers would have been very ready to admit; for, on their principles, it may be equally affirmed, that a person totally ignorant of the being of God, or one who denies his existence, may feel all the obligations of virtue; and that an atheist may be the most virtuous person in the world. This must be the natural consequence of making virtue the result of a moral sense; for such a faculty should convey its intimations to the mind as infalliably as perception; and the atheist and the believer should equally feel its power.

The common sense and experience of mankind revolt at such an idea; and, till modern times, neither moralists nor legislators have ever imagined that there is a moral sense in man of sufficient efficacy to regulate his conduct, independent of the belief of a God, and of a future state. The practice has always been to impress on the minds of men a conviction, that the moral precepts which they were required to obey were the laws of the gods, and that they must be accountable at their tribunal for the neglect of them. This appears to us to be not only good policy, but sound philosophy; and to lay the only sure foundation on which we can ultimately rest the feeling of moral obligation.

A man who has no idea of a God or of a future state, may, nevertheless, be trained to a certain course of conduct conformable to the general views of the society in which he lives. If he acts in opposition to these views, he will be blamed or punished; for he then breaks through the rules of the confederacy; and he may be expelled from the community, as we are told the rooks do with their pilfering companions, when they are detected in the act of carrying off the materials of their neighbours' nests. To avoid punishment or shame, then, is sufficient to induce conformity to established rules and customs; another motive will be furnished in the praise which attends every man who respects public opinion; and he who is forward in defending the rights of the community, will be courted and applauded for the protection which he affords. Here, then, is a standard of approbation and disapprobation, founded in public opinion, which is often iniquitous and absurd, when considered in reference to higher principles, or the rights and interests of other communities; and we have thus a moral condition, if it can be so called, of human nature, without any reference to a moral governor. We believe that many large communities exist in this state, fettered by inveterate prejudices, and referring to them with promptitude as the laws of their nature.

But there are many laws of our nature which are not moral laws at all. It is a law of our nature to eat when we are hungry; it is a moral law which says, *Thou shalt not steal.* In this view, the law of our nature is totally distinct from the law of moral obligation. The former arises from instinct or appetite, or from prejudice, to which custom has given the force of a law. The law of nature is limited by the moral law, which defines the boundaries of our enjoyments. This moral law is neither instinctive nor intuitive; it can only be discovered by reference to revelation, to experience, or to observation of the obvious designs of providence. It is true that moral laws are also laws of our nature, that is, they are framed by the author of our nature for our happiness and improvement; but they become obligatory on our conscience, only in consequence of our referring them to the will of a superior, to whom we owe allegiance, and who is entitled to it from his uniform kindness and benevolence, as well as from his sovereign power and authority.

The ideas of *right* and *wrong* are acquired at such an early period, and confirmed by such a course of constant discipline, that we are apt to consider them as instinctive feelings, or as original independent intimations of conscience; and the opinions which tend to modify or controvert this doctrine are generally viewed with some suspicion, as being conceived to have a tendency to shake the eternal foundation of moral virtue. In so far as our particular opinions are concerned, this alarm is entirely groundless; for we most zealously contend for the eternal unalterable distinction between right and wrong; but, we contend, that the mind does not possess in itself any particular power or faculty which decides, *suo jure*, on the moral fitness of actions; and that its decisions on this important point must be settled by showing the conformity, or non-conformity, of any action with the general order of nature, to which our feelings, faculties, and powers, are adapted. By this means, we perceive that the distinction between right and wrong is not fanciful, nor casual, but fixed and permanent, having its foundation in the ordinations of providence, which God has made us capable of observing, and which are presented to us every day, and every hour, that we may be trained to the functions of moral beings.

What use is there, then, for a moral sense, to perceive what is every moment of our lives pressed on our notice, and rendered familiar to our understanding by a thousand instances? Is it a moral sense which teaches parents the duty of loving their children? No, it is an instinctive feeling; it is exactly the same with that which regulates the lower animals, who might, with as good reason, urge their pretensions to a moral sense, on the ground of parental affection? Is it a moral sense which enforces the duty of conjugal fidelity, and shows the beauty of this virtue? No, this duty results from perceived necessity and expediency. Is there a moral sense which tells us that polygamy is improper? No, but we soon perceive it to be so from the burden and inconvenience, the jarring and discomfort which necessarily arise from a double or divided family. We should like to see how the impropriety of this practice could be evinced on the principle of a moral sense. On our principles there is no difficulty; for, besides the personal inconvenience which it produces, we can show that the order of nature is in favour of monogamy; the birds of the air, and the beasts of the field, separate into pairs, and during the season of their loves remain faithful to each other; and the same lesson is inculcated on the human species by the proportion between the sexes; an argument which the author of our religion did not disdain to employ, when he said, *he that made them at the beginning made them a male and a female.* Is it a moral sense which proclaims the virtue of patriotism? No; we are trained to it from our infancy, in consequence of those powerful associations which arise from common laws, and common religious feelings, and common protection, and common interest, all which cement the population into one body, and knit the soul of the community into one common feeling. Does any moral sense teach us our duty to God? No; our feelings often revolt from this duty, whilst our reason can point out a thousand arguments to enforce it.

Our readers will perceive that we have been arguing against a *moral sense*, only in the light in which it has been viewed by several eminent modern philosophers, such as Butler, Reid, Stewart, &c. as a distinct power of the mind, enabling it to perceive the moral beauty or turpitude of actions; and whilst we dismiss it, in this sense, as totally unnecessary, we have endeavoured to shew that there is a radical and essential distinction between right and wrong, fixed by an unalterable law, which we are compelled to recognise, because we cannot recede far from it without ruining our happiness.

We are not to seek, then, for the law of moral action solely in the mind itself; this would carry us back to the innate ideas of Descartes; the mind collects it partly from its own feelings and faculties, partly from the bodily capacities and functions, and partly from the order of nature, or the circumstances by which we are surrounded, which are ordered and disposed by the author of our nature, and influence materially our feelings, our opinions, and our actions. By comparing all these things together, we learn to distinguish between what is local or accidental; and what is fixed and permanent; and we perceive distinctly that the line of conduct resulting from the knowledge thus acquired, is not only consistent with the will of heaven, as intimated by the course of Providence, but is also perfectly consistent with our own happiness. It is only by this enlarged view of the subject, that we learn to correct the narrowness of private feeling, and to consider our own happiness as identified with the public good. An individual who looks not beyond himself, would be disposed to view many things that befal him as exceedingly wrong, and to regard them with the strongest disapprobation; but when he considers these things as happening by the fixed ordinations of Providence, and that, of course, they must be useful in their general tendency, though disastrous to him, he then views himself as a fellow-subject under the same moral government, and learns to approve whatever promotes the plans of the Supreme Legislator. He then learns that true self-love and social are the same; and he learns, moreover, that *to be virtuous*, and *to consult his own interest*, are, in fact, synonymous expressions. Partial views of expediency, or limited conceptions of God's moral government, or turbulent and ungovernable passions, may often make these expressions appear not only different, but opposite; but they are identified by the nature of things, and the appointments of heaven. And we are inclined to think with King, that the disagreement of authors respecting the criterion of virtue, is rather apparent than real; and that "*acting agreeably to nature or reason*, when rightly understood, would perfectly coincide with *the fitness of things*; the fitness of things, as far as these words have any meaning, with *truth*; truth, with *the common good*; and the common good with *the will of God*."

It follows, from what we have already advanced, that whatever tends to promote the best interests of man must be right, and conformable to the will of heaven; and that, in searching for a rule of moral conduct, we will always find it to coincide exactly with that which promotes the real happiness of man. Much misconception has arisen on this subject, from confounding the motives with the rules of action. Were there no sinful bias in human nature, and no tendency to excess in its original passions, the motives and the rule would always coincide: in that case, whatever man willed would be right, and his own inclinations would be an infallible rule of right conduct. But as it is evident that the passions often act with undue violence, and are directed to improper and illegitimate ends, the only rule that we can have for the management of them is, to consider the consequences which they produce, in their various bearings on our character, our present happiness, and our future hopes. If they contradict any intimation which we have received from the word of God, or the light of nature, we have reason to feel alarm: but if these are not contradicted, whilst our present happiness and respectability are promoted, we have the concurrence of every species of evidence to prove that the passions, or appetites, or desires, have been legitimately indulged, and directed to proper ends. We do not see any rule, then, by which we can judge of the proper degree in which any appetite or passion ought to be indulged, but by the expediency of the results to which it leads; and having learned by experience and extended knowledge what is most conducive to our own and the general good, we henceforth conclude that this is an object of rational pursuit; we studiously dismiss every motive that would divert us from the attainment of it; and the rule and the motive are again brought to coincide, as must have been the case in a state of perfect rectitude.

Mankind act at first without minutely calculating consequences, or having any regard to remote expediency; for they are trained to action either by authority, which they dare not disobey, or by instinctive feelings, which they are not inclined to resist. In this way, they often acquire habits which stick to them through life, and which they seldom examine, with a view to ascertain whether they be founded in truth and reason. When, however, they have been led to think, they soon begin to perceive that the habits which they have acquired, and the feelings which they have blindly obeyed, are referable to a general law, whose utility they are forced to recognise.

This is the general situation of mankind; they are, from their infancy, moulded by education, and trained to moral habits insensibly and involuntarily; but not accidentally; for every system of moral education has a foundation in nature, though it may be strangely distorted by circumstances, and scarcely reducible to the ordinary habitudes of moral action. When once their knowledge is extended, and they are able to examine the foundation on which their actions rest, they either find them, or endeavour to make them, consistent with that general plan which reason compels them to recognise, and to ascribe to an intelligent and benevolent ruler, whose laws they feel themselves bound to obey.

Those feelings, then, must be pronounced worthy of moral approbation, which give rise to actions which are salutary in their consequences, useful to ourselves, and beneficial to society; and calculated alike to promote our present happiness and our immortal hopes.

This is nearly, if not altogether, the doctrine of Expediency, as taught by Paley, which has been so generally condemned, and so little understood. It is the very principle, however, which seems to regulate all the proceedings of the Almighty; the tendency of the whole being to promote the general good; and could we detect any thing in the economy of Providence, decidedly malignant in its aspect and tendency, we should be forced to exclude benevolence from the list of the divine perfections. But as we pronounce the ways of God to be good, from perceiving that the result is beneficent, can we hesitate to pronounce our approval of human actions, when their tendency coincides with the plans of Providence, and when their end is to promote the general good? But there are some who seem as if they never could be satisfied, unless virtue and interest are set at variance, and happiness and duty rendered inconsistent. They seem to be influenced by the same principle as the Religionists, who seek for merit by austerities abhorrent to nature; or as the worthy Father, who wished he had been commanded to believe what was impossible, that he might have had it in his power to give a satisfactory evidence of his faith. Who can hesitate to explode such notions as hurtful follies? And we aver, that they do not think more soundly, who imagine that virtue must be inconsistent with their present interest and happiness. In prosecuting a course of virtuous conduct, we may be compelled to forego some temporal advantages, which may fall to the lot of persons whose consciences are less scrupulous than ours; but this involves no forfeiture even of present happiness, since we have more satisfaction in the approbation of our consciences, or in the hopes of future reward, than we could have enjoyed from the gratifications which we voluntarily renounce, after a due calculation of consequences.

If, therefore, by *what is expedient*, we understand not merely that which promotes our present interest, and private gratification, but that which is most conducive to the general happiness of ourselves and others, for time and for eternity, we may certainly consider this kind of expediency as a test of the virtue of human actions, unless it can be proved that God has given some other rule inconsistent with these principles. But this is impossible; the Author of our nature is not such an unreasonable task-master, as to command the performance of duties from which we can derive neither profit nor pleasure. His precepts are sanctioned not only by the paramount authority by which they are enjoined, but also by their own reasonableness; by their adaptation to our circumstances; and by their tendency to promote our true happiness. We have thus every conceivable inducement to virtuous conduct, since it is found to be not only conformable to the will of heaven, and to the law of conscience and of reason, but also perfectly consistent with the best interests of man. To suppose that what is expedient, in the extended sense in which we have understood the term, can by any possibility be wrong, would be to subvert at once all our ideas of the moral government of God, which can be understood only by the perceived tendency of the plans of Providence to promote some good and beneficent end. We may surely, then, judge of the moral character of human actions by their tendency to promote the best interests of man; and we may find the origin of moral approbation, by applying to the actions of men the same *criteria* by which we judge of the wisdom and goodness of God.

It cannot be denied, that the doctrine of *expediency* may be grossly abused; it is the abuse of it that gives rise to all the aberrations of human conduct; for, whenever any man deviates from the straight path of rectitude, he proposes to himself some present or ultimate advantage; but his views are limited to selfish and temporal gratifications; and he forgets the duties which he owes to society, and to himself as the heir of immortal hopes. But the doctrine is not answerable for these abuses and perversions of it; these must be charged to the account of the headlong passions of men, which, for the sake of a little present gratification, make them overlook their duty as rational, social, and immortal beings. Nor can it be denied that we are exposed to numberless temptations, which induce us to take very short-sighted views of expediency, and to consult our own comfort at the expense of the general good; but reason and conscience are given us to combat these temptations, and to raise us above narrow and contracted feelings, to the rank and dignity of moral beings. So powerfully do these principles operate, and so distinctly do they proclaim that man is formed to take an interest in the common welfare of his species, that there is nothing of which he is so much ashamed as to be convicted of selfishness and want of feeling for the distresses of others.

It is observed by Dr. Smith, that the loss of a finger will cause infinitely more uneasiness to an individual, than to hear of the loss of the whole empire of China; yet, he observes, that no man would hesitate to make such a sacrifice to save so many millions from destruction. The observation holds true with regard to cultivated man, whose mind has been trained to observe the various dependencies in human society, and to see the principle of philanthropy, generated at first in the narrow family circle, gradually diffusing itself through the whole family of mankind.

> Friend, parent, neighbour, first it will embrace,
> His country next, and next all human race.

But an uninformed savage who has not learned to read the will of Heaven, in the ordinations of Providence, and to perceive that his own happiness will be promoted by expanded feelings, would not give one joint of one finger to save half the world from ruin; and this, surely, is as clear a proof as can be desired, that philanthrophy is not the result of any particular moral sense or natural feeling, but the consequence of enlightened reason, of improved principle, and of matured wisdom.

Thus, from limited views of expediency, very great errors may arise; for a man is extremely apt to consider every thing as inexpedient, which thwarts his views, or obstructs his favourite pursuits. To this contracted principle may be ascribed all the ravings of party spirit, and the aggravated colouring in which every partisan represents his opponents. These are exhibitions of human character, which sound wisdom will teach us rather to pity than condemn; for we can easily perceive that no man can have any great liking for qualities which eclipse his own fame, or prevent his own advancement. When placed beyond the possibility of interfering with our interests, we can praise and admire them; when death removes the grounds of emulation, we can shed a tear over the ashes of a rival, whom, when living, we feared and detested. *Extinctus amabitur idem.* Though this is not exactly what it should be, and though it presents not a very flattering view of human nature, yet it must almost necessarily take place in a complicated state of society, where so many are contending for the same prize, and eagerly desiring the same enjoyment. In such a state, one man's interest must often stand in the way of another's, and the prosperity of one must often be at the expense of another's comfort. Hence arise envy, jealousy, and detraction, qualities extremely odious, but naturally springing out of limited views of expediency and interest, and not easily corrected, we fear, by considerations merely moral; for, though reason may easily show their impropriety, it cannot so easily subvert their influence in the human heart. But let it be remembered that the evident design of the Supreme Lawgiver is, to promote the general good of the human species; and that when this object is accomplished, individuals are not to consider their partial inconveniences as any exception to the divine goodness. If they suffer in one respect, they may be improved in another; the loss of worldly wealth may be the acquisition of substantial wisdom; and the trials to which they are exposed may be the means of calling forth their mental energies, and of exhibiting a display of virtues and endowments to meliorate and improve the world.

Let it then be kept in view, that man is accountable for his actions at a higher tribunal than that which is constituted either by conscience or public opinion, (and without this consideration there can be no moral responsibility,) let this be kept in view, and there will be little danger of abusing the doctrine of expediency, or of making it subservient to low and selfish gratifications. Every individual will then consider himself as bound to promote that general happiness which he sees so carefully consulted and provided for by the Parent of the Universe; even though, in doing so, he should be compelled to forego some private advantage of his own. But it is not generally necessary to make such a sacrifice; for public prosperity cannot possibly arise out of general individual misfortunes; and those measures which are best for the whole, will generally be found best for every individual of which the aggregate of society is composed.

The same observations hold true with regard to the general intercourse of nations with each other. Justice, in the long run, will always be found to be their best policy; though the violation of this principle may often promise many great and decided temporary advantages. It is not long since we heard it proclaimed, in the face of the whole world, that it was expedient for the safety of the French empire that Spain should be annexed to its already overgrown possessions. The same argument has always been employed, wherever a powerful nation wished to invade the rights of its feebler neighbours; and in all cases the general result has been the same; either an enthusiastic spirit of resistance has been produced, which defeated the design of the aggressors; or passive acquiescence begets in them a supineness and effeminacy, which soon render them fit and easy objects of vengeance.

When this merited retribution occurs, it is very generally reckoned an interposition of Providence to punish the guilty. We conceive this opinion to be erroneous. No interposition is necessary in such cases; they fall under the general laws of an overruling Providence; and by the operation of natural principles and feelings, they bring their own corrective along with them. We see, no doubt, the hand of Providence, whenever the foolish reap the fruits of their folly; or when the presumptuous fall by their own pride, or the profligate by their own excesses. But there is nothing unusual here, to deserve the name of an interposition; all these instances are embraced by the ordinary principles which regulate the dispensations of Providence, and which have fixed, with unerring certainty, the consequences of human conduct. Were it possible to preserve moderation, when in possession of absolute power; or prudence, when crowned with continued success; or energy, when wallowing in luxury; or abstinence, when unrestrained by principle; in such circumstances, it might be necessary for the Supreme Ruler to depart from the usual principles of his government, and to interpose in an extraordinary manner to punish the guilty, or to break the rod of the oppressor. But the case is amply provided for by the ordinary arrangements of Providence; and the circumstances which we have stated never fail to produce such consequences as tend to bring mankind back to the sound principles established by the law of God, and illustrated in his moral government of the world.

We trust, then, that it will appear, from what has been said, that whatever is right, and just, and proper, is also most expedient, both for individuals and for nations; for the ways of Providence, which evidently sanction these principles, never can be supposed to direct mankind to a course of conduct which will be ultimately unprofitable. This proposition, indeed, will be assented to by the most scrupulous moralists; and yet is it not perfectly convertible, and may we not say, with equal propriety, that whatever is ultimately and essentially expedient for men, must be right, and agreeable to the will of Heaven? Would it not involve a monstrous absurdity to say, "this is, *in every respect*, most expedient for you, but it is wrong, you must avoid it?" For what can influence the conduct of any human being, but a regard to his best interests? It is true, indeed, that what is expedient for one particular purpose, may be wrong; but this is only because it is inexpedient upon the whole. This was the case with the plan of Themistocles for burning the combined fleets of Greece, that the Athenians might be undisputed masters of the sea. He had stated publicly that he had devised a measure of the utmost consequence for increasing the power of Athens, but that it could not be divulged without defeating the execution of it. Aristides was ordered to communicate with him; on hearing the scheme, he instantly repaired to the assembly of the people; and without informing them what the measure was, declared, that nothing could more effectually promote the superiority of the Athenians, but that *nothing could be more unjust.* The feelings of the people, on this occasion, acted with instinctive promptitude; and, relying on the opinion of one whose name was identified with that of justice, they ordered the measure to be rejected without farther examination. Had they acted differently, this illustrious Athenian could easily have shown them, that mutual good faith was essential to the peace and the intercourse of nations; and that, without this, they must be perpetually engaged in wars of extermination against each other.

After all, however, we are more anxious to rescue the doctrine of *expediency* from the undeserved obloquy to which it has been exposed, than to found on it our system of morals. We consider it, particularly as it is explained in the writings of Paley, as a beautiful illustration of the wisdom and benevolence of the divine government, in having made the duty of man, in every respect, consistent with his best interests. But we conceive the principles of morals to rest on a still simpler basis, and to be pointed out by circumstances and facts in the constitution of our nature, long before we have any idea of their general expediency or unfitness. It is only after the mind is enlightened by varied knowledge, and the principles improved by patient culture, that we discover our real interests, and discern the wisdom and goodness of the divine government. Till we reach this point, we are pretty much in the situation of children whose humours are crossed by a parent's authority, and whose views of expediency are very different from his. They find, however, at last, that he understood their interests much better than they did themselves, and that obedience was both their interest and their duty. There cannot be a doubt, that we will ultimately make the same discovery with regard to the law of God: in the meantime, it is our duty to listen to the plain intimations by which his law is enforced; in the confidence, that in the end we will find the result to be both profitable and expedient.

If, then, our duty as moral agents be perfectly coincident with our best interests, we may safely assume expediency, in the enlarged sense in which we have considered it, as a sure *criterion* of virtue: for it is impossible but that which is most conducive to the temporal and eternal interests of man, must also be agreeable to the will of God, who, in all the arrangements of his providence, has obviously consulted our happiness.

If we admit that this is a fair *criterion*, we may perhaps be able to throw some light on the much agitated question, "To what principle in our nature we are to ascribe the feeling of moral approbation." For the question will then be reduced to this, What is the principle which enables us to decide respecting our best interests? And this question will be answered by considering what principle, or principles, are employed in comparing different actions, in anticipating consequences, in contrasting the effects of different gratifications, and in taking into view the general interests of man, as a social, rational and accountable being. Lest we should err in assigning to one principle what, in fact, we consider to be the results of several, we say, in general, that these operations are to be ascribed to the intellectual part of our nature: for we do not pretend to be acquainted with any principle but reason, which can show us the obligation to obey any law. Where visible authority is interposed, fear would compel obedience, even when the law is unreasonable: yet even here we cannot exclude the province of reason, which compares the different results of obedience and disobedience, and compels us to adopt the course most likely to ensure the least injury, or the highest satisfaction.

Conscience is generally supposed to be the chief agent in these decisions: and its power is indeed great; it acts with a force which is thought inconsistent with the nature of a secondary or factitious principle, and is appealed to as a sovereign arbiter in all discussions about right and wrong. It may always be safely trusted, when enlightened by knowledge and guided by reason: but without their assistance it is a dangerous, and often a destructive adviser; clearly evincing that it has no independent jurisdiction, and is possessed of no infallible certainty of decision. It is merely a mental habit, arising out of the circumstances of our nature, and strengthened by the most powerful associations, and the most interesting recollections: and is disciplined by constant use, till it acts with a rapidity and force which makes us forget every thing but the emotions which overwhelm us.

Suppose we should wish to enforce any one of the moral virtues, we can derive arguments both from the positive command of the Supreme law-giver, and also from many accessary circumstances which recommend present obedience, independent of more remote views of advantage. Let us see, for example, how we would recommend the virtue of *patience*, from considerations of a moral nature. In the first place, we feel that impatience renders us unhappy: this is a hint from our own nature, to teach us to repress our headlong passions, and to wait patiently for the desired consummation. In the next place, we see that impatience does not promote, but rather retard, the accomplishment of our wishes: here reason lends its suggestions in aid of our feelings, to strengthen the great moral lesson of patient endurance. But this is not all; the same lesson is enforced by the whole order of nature, and we are actually trained to it by the usual economy of providence. No man expects to reap on the same day in which he sows; no man expects all the time to be annihilated which lies between him and enjoyment: he is compelled to wait; and he cannot but see that it is best to do it patiently. We perceive that a certain portion of time, and a certain quantity of labour, are necessary for the production of certain effects, and that cheerful application is the best antidote against the irksomeness of labour, and the tedium of hope deferred. We see also that time is necessary for the evolution of the plant, and for its advancement to strength and beauty; and that we should completely blast our hopes, did we not patiently wait for the process and period of fructification. How beneficent, then, is our law-giver, who presents so many inducements to observe the precepts which he has enjoined, and who in fact makes the system of nature, and the arrangements of his providence, monitors to point the way to happiness and duty. By what arguments do we enforce temperance? Does any moral sense tell us how much we should eat and drink? No: but a rule no less certain is given us by the author of our nature: for we feel excess to be hurtful to our health, or we feel that it impairs our faculties, and gives undue strength to our passions; or we perceive that it will ruin our fortune, and thus ultimately destroy all our means of enjoyment. Any one of these reasons is sufficient to enforce temperance, and to show us that it is a virtue sanctioned by the wisdom of the Supreme Law-giver. Nor are we without arguments for this virtue drawn from the constitution of nature: for the earth produces enough for the temperate subsistence of its present inhabitants; but were we to double the consumption, one half must be starved, or the whole be inadequately fed.

All that we are anxious to establish at present is, that we are trained, to a certain extent, in the practice of morals by the very constitution of our nature, and that of the external world, before reason shows the expediency of a moral rule; and that a foundation is laid for the ideas of moral approbation or disapprobation, in the simple feelings of liking or aversion, which have been produced in our minds by conformity or nonconformity to the laws imposed on us by the author of our nature; which laws, in the first instance, we blindly obey, or heedlessly violate, till experience extends our knowledge, and shows the immoveable basis on which God has established the practice of virtue.

We are far from wishing to fritter down the moral feelings, and reduce them to mere operations of intellect: we are anxious, on the contrary, to preserve entire the enthusiastic love of the *pulchrum et honestum;* we wish to see it so firmly established in the heart, that it may act with intuitive quickness, and instinctive accuracy: and God has taken care that it shall do so, unless voluntarily and obstinately resisted: for we are trained to it every day; and the mind is as little sensible of any effort in distinguishing between the ordinary principles of right and wrong, as when it distinguishes by the ear the notes of a well known tune. Thus *habit* acts as the auxiliary of reason, and supplies the place of those instinctive principles which some contend for as necessary to produce the idea of moral approbation. This habit is neither the result of reason nor of accident; it arises out of the constitution of our nature, and the circumstances in which we are placed: and the office of reason is, to ascertain whether it has been legitimately formed, or has grown out of misconceptions of the human mind, and erroneous views of the nature of things. Did not our passions exercise an undue influence, and distort, as it were, the arrangements of providence, our habits would all be regular, and would be formed according to the law of nature, which is the law of God. But since there are so many things to mislead us, reason must exercise an impartial scrutiny, and endeavour to distinguish between those associations which are natural and those which are spurious; and between those habits which are accidental, and those which are founded on the immutable order of things.

To favour the opinion that a moral sense is necessary to give the idea of moral approbation, it has been alleged that the reasoning faculties cannot give us any idea either of the beautiful or of the good.* To be sure, reason does not produce the idea of the sublime or beautiful, but it enables us to analyse the principles on which it depends: and, in the same manner, goodness and moral beauty are not the creatures of our reason: it only recognises them as established by the law of heaven, as agreeable to the nature and circumstances of man, and as founded on habits which these circumstances necessarily produce.

But the fancy of some moralists is, that after reason has shown a measure to be consistent with the general good, and to harmonize with the general system, a particular sense is farther required to give the perception of moral beauty. This is similar to the whim which we have endeavoured to explode from intellectual philosophy; (See Conception and Logic,) viz. that after the reason, or whatever power it may be called, has collected the parts of an idea, or conception, into one whole, yet still a distinct faculty is required to act as gentleman usher, and introduce this stranger to the presence of the mind. We have shown that certain objects presented to the senses, are found at once to be agreeable or disagreeable. Two well proportioned pillars please the eye—two distorted or irregular ones offend it—harmonious sounds are agreeable to the ear, discortant ones are displeasing. But it often happens that the objects of perception are presented to us in such a complicated form, that we can, at first, discover neither beauty, nor regularity, nor harmony: by a process of reasoning, and patient investigation, however, we discover at last beautiful arrangement, and mutual subserviency, and adaptation of parts. The mind is then enabled to take in the whole at one glance, in consequence of the connection which reason has established among the parts; and can pronounce on the beauty or deformity of the *tout ensemble* with as much readiness as on simple proportion, when presented to the eye.

The same thing, we believe, takes place in our judgments respecting the merit or demerit of actions. We cannot but perceive, for instance, that cruelty is wrong; we dislike it when practised on ourselves, on our children, on our relations, or our friends: and, with these feelings, it never can be an object of moral approbation in any circumstances; for we soon acquire a general abstract dislike of any quality that is particularly offensive to us. In consequence of this, our judgments are often infected by prejudices which have arisen out of our own particular circumstances, and which give an undue bias to our opinions on general questions in morals. This, however, is only the abuse of that principle which leads us to decide, with almost intuitive readiness, on the merit or demerit of actions; and which has its foundation in the liking or aversion which we feel, when we ourselves are the objects of these actions. But perhaps the character of actions is not, at first sight, very apparent; we have, perhaps, complicated motives to examine, and a variety of circumstances to consider, before we can form a just estimate of the action subjected to investigation. We discover at last, however, we shall suppose, that cruelty or injustice lie at the root of the whole, and that every part may be resolved into these principles: in these circumstances, our earliest and most powerful associations lead us to pronounce a decided disapprobation of those qualities which we have been trained to dislike, which we hate when exercised towards ourselves, and which we soon learn to hate with abstracted unmixed dislike, in whatever circumstances they may appear.

Is not this the origin of that sympathy which forms such a remarkable feature in human conduct, and whose influence on our moral perceptions Dr. Smith has so beautifully illustrated? Taking sympathy in its most ordinary sense, as a feeling extended towards those who endure suffering, it obviously arises out of our own private feelings. Suppose the suffering to arise from cruelty or injustice, is not our sympathy for the sufferer excited, primarily, by our antipathy to the offence by which he suffers? There is an ingenerated abhorrence of the crime, and this elicits our affections and exertions in behalf of the sufferer. We believe this to be the real origin of our sympathy, in the sense in which we have at present understood the word; and we think it would not be difficult to show that it has a cognate origin, in whatever acceptation the word can be used. It is not, then, as Mr. Stewart alleges, a

* Phil. of Rhet. vol. i.

principle superadded to our moral constitution, as an auxiliary to the sense of duty; sympathy is a name invented to describe that particular effect which the sense of our own injuries or sufferings produces on our feelings, when we contemplate the injuries or sufferings of others; in which case our hatred of the injury makes us espouse the cause of the sufferer, and teaches us to adopt him as our ally in repelling the evils which beset humanity. We are perfectly sure of his concurrence, and rejoice to have found a person animated by our own views and feelings, and bound to us by a powerful common tie.

We are aware that sympathy is generally considered as a mysterious original power, which instinctively prompts the heart to feel for the miserable. This notion is disproved by the fact, that those who suffer least, have always the least sympathy; and were there any wholly exempted from suffering, we have reason to conclude that they would be monsters of inhumanity; unless they were trained to a kind of artificial benevolence, and thus taught to relieve sufferings, which they neither can sympathize with, nor comprehend. They, on the other hand, who have suffered most, have always most tenderness of heart, and feel the most anxious desire to relieve the afflicted.

Haud ignara mali miseris succurrere disco.

We hold, then, that all those things which are morally wrong, are either offensive to our feelings, or injurious to our interests. This is a safeguard to our virtue, provided by the wisdom of Heaven; and the very dislike of cruelty or injustice, is tantamount to moral disapprobation: for though, in many cases, there may be dislike, without moral disapprobation, yet this is only when moral agents are not concerned. A voluntary offence must always be viewed with marked disapprobation, as being an offence against the comfort and security of human nature, and against the general laws which God has appointed to regulate our feelings.

It is sometimes, indeed, extremely difficult to convince men that certain species of moral evil are hurtful to their interests; because perverted feelings counteract the influence of conscience and reason, and keep the mind in a state of torturing suspense between inclination and duty. These are moral *Idola*, which prevent the mind from recognising the obligations of virtue, in the same manner as the *Idola tribus*, &c. prevent it from discerning the obvious conclusions of right reason. But let the passions be lulled asleep, and let the injurious tendency of any practice to which we are addicted, be then demonstrated, and it will instantly be viewed with moral disapprobation, or rather with compunction, because we feel that it is a voluntary injury which we have inflicted on ourselves; and self-condemnation aggravates the unpleasant feelings which always accompany moral disapprobation. There are fewer obstacles to the exercise of a sound judgment in estimating the conduct of others: we disapprove, with instinctive readiness, of what is vicious, and commend, with equal promptitude, what is salutary and useful; not from any selfish views of benefit or injury, but because we have actually acquired an abstract love or dislike of certain qualities which have affected us; and that not accidently, but by the constitution of our nature, and the arrangements of Providence.

But perhaps it may be thought that greater uniformity in morals might be expected, if the principles which lie at the foundation of them are thus general, and fixed immutably in the constitution of things. In answer to this, we may observe, that though there are numberless circumstances which diversify the aspect of moral conduct, yet we are acquainted with no instances in which the ordinary principles of morals are reversed. We know of no nation in which a mother does not love her own child, or in which a son does not, in some way or other, honour his parent. We hear indeed of some tribes in which it is customary for children to put their aged parents to death. Supposing the fact to be fully ascertained, it would not militate against our assumption of *filial duty* as a general law of our nature. We may easily conceive that this unnatural practice arises from a mistaken sense of duty, and that the son reckons it an act of piety to terminate or prevent the sufferings of his aged parent.—We are told that, in Sparta, theft was reckoned a virtue: No such thing; but dexterity and adroitness were reckoned useful qualifications, as being akin to the stratagems of war, to which the whole policy of the state was made subservient. Theft was punished there, as it is in every other place, where a distinction of property exists; but he who stole, not from necessity or inclination, but to sharpen his powers of stratagem and cunning, was commended, as these qualities were deemed useful to the state.—In many nations, the sexual intercourse is extremely loose; yet we know of none in which the principle of appropriation does not obtain, and in which the relations of husband and wife are not recognized.

If we consider the worship of God as a moral duty, in which light it is undoubtedly to be viewed, we shall see the most immense diversity of absurd rites, and monstrous objects of superstition; yet, amid all these aberrations of the human understanding, the leading principle of religious worship is recognised, and the duty of man to adore a supreme power is acknowledged.—In short, amid all the diversity of human conduct, we can always trace some leading connecting principle, though infinitely varied, according to the circumstances of society, in regard to knowledge, education, and refinement. In some instances this principle is faintly developed, in others grossly perverted; but in all exhibiting features of affinity, which compel us to recognise its common origin, and to see that it has an immutable foundation in the arrangements of Heaven.

The history of the various nations which have flourished on the face of the earth, is chiefly interesting from observing the development of the same moral principle, from the first simple elements on which it is founded, till it is carried to the highest improvement and most extensive application of which it is susceptible. We are often struck with the singularity of manners and customs which we observe in different states, but our wonder vanishes on being made acquainted with their circumstances, prejudices, and habits. That which at first sight appeared singular or anomalous, is discovered to be natural, in the imperfect state of improvement which they have reached. It resembles the feelings of a child, which, though springing out of human nature, and laying the foundation of the attainments of manhood, yet appear removed at an infinite distance from the disciplined feelings of maturer years. Thus we see certain important principles very imperfectly exemplified in particular states of society: they are struggling with prejudices which tend to repress them, and emerging from the midst of circumstances which for a while weaken their influence. They are, however, accommodated to the taste of the nation at the time; and a premature reformer would in all probability rivet the chains of prejudice, or ensure his own destruction; whilst he who watches the tide of public feeling, and seizes the proper moment for innovating on public opinion, will carry the whole nation along with him in a triumphant career of improvement, and will lay the foundation of principles and feelings which will never cease to operate till the nation shall cease to exist.

We are often astonished to see how slowly and reluctantly some of the most obvious principles of political morals are recognised. The Lacedemonians put to death the prisoners whom they took at Ægos Potamos, though they were fighting the battles of their country. Indeed the most refined of the ancient nations generally acted on the most contracted principles of political expediency; and we more frequently meet with instances of generosity in the case of a successful despot, than in that of a free and high-minded people. How long was it before the principles of civil liberty were understood, and how imperfectly are they still understood, over the greater part of the world. Yet nothing can be more obvious that the foundation on which they rest. It is evidently this, that no man has a right to restrain the freedom of another, so long as he does not use it in a way injurious to the public interest. Yet this principle is counteracted by the love of power which every man feels, or by the advantage which he may derive from supporting a successful usurpation. In consequence of these conflicting principles, there is a constant struggle between the love of freedom on the one hand, and the love of power and the servility of interest, on the other; and even when freedom prevails, it cannot temper its own triumphs, but, by running into licentiousness, subverts its own rights, and often produces a prejudice in the mind against its fairest claims.

But whilst we contemplate the gradual and imperfect evolution of the moral principle in various states of society, we see at the same time the beauty of God's moral government, which makes the same principle which consolidates the rudest states cement the most polished and the most powerful; expanding with their growing wants and their advancing knowledge, till at last it gives birth to feelings, of which the ruder mind could form no conception. Such a view is surely well calculated to produce liberality and mutual forbearance. We might almost as well find fault with a man for being born blind, as with an illiterate savage for not feeling the finer moral sensibilities of our nature. The faculty is not yet developed, because no excitement has been applied to it; and the individual thus circumstanced is like a child who has an ear for music, but, from want of experience and training, cannot as yet distinguish one tune from another. And the same estimate which we apply to the moral state of nations, we ought likewise to apply in judging of the characters of individuals. How often do we see incongruities which we lament, and which yet do not, on a fair estimate, amount to moral delinquencies! They arise rather from some obliquity of the understanding, which has been disturbed by inveterate prejudice, or fettered by invincible ignorance: and we ought to regard persons thus unhappily situated, with the same indulgence as we view nations a century or two behind our own, in point of general improvement. In fact, every individual, in his moral progress, has to go through all the stages which have conducted nations, during the lapse of many centuries, to their highest pitch of moral and political improvement. We see him, for instance, at one time distinguished by the prejudices which characterized the tenth century. We see him struggling, with difficulty, through the mists of ignorance, till at last some event, similiar to the revival of letters, or the art of printing, or the Reformation in religion, agitates his mind, rouses his faculties, and raises his feelings to the highest tone of moral refinement.

Hitherto our attention has been directed almost solely to those great general principles which God has established in the constitution of our nature, or the arrangements of his providence, to direct us in that course of duty which is most consistent with his will, and with our own happiness; and we have endeavoured to show that we are evidently directed, and to a certain extent forced into the path which we ought to follow, in fulfilling the will of Heaven, and prosecuting our own happiness. Our object has been to show that the principles of morals, so far from being accidental or conventional, are fixed and immutable; varying occasionally so far as the exhibition of outward actions is concerned, but permanent in their nature and character. Our instincts, our appetites, our bodily powers, our mental faculties, together with the whole constitution of nature, point to the same goal, and conspire to produce the same important results. Experience and observation confirm these obvious intimations, by showing us that *what we ought to do*, is always most consistent with our happiness and interest, and that whenever we violate the invariable order prescribed and confirmed by so many sanctions, the transgression never fails to bring its own punishment along with it, and to remind us of the eternal law by which our moral actions and feelings should be regulated, and shall one day be judged.

But whilst our duty is thus enforced by so many considerations, it must at the same time be remembered that all our feelings have a tendency to excess; that every passion seeks its immediate and direct gratification; whilst such indulgence is in general utterly subversive both of happiness and moral order. Hence the unceasing conflict between our passions and our reason, in which the latter is so often worsted; and hence all those moral evils which desolate the world, which introduce guilt into the conscience, and misery into the abodes of men. To obviate these inconveniences, is the object both of moral studies, and religious instructions, though these frequently prove ineffectual to correct the inveterate habits arising out of vicious indulgence. There is, however, no natural impossibility of doing so. Any vicious habit may be corrected, if motives sufficiently powerful are suggested. Let a man be convinced of the odiousness and criminality of vice; let him be persuaded that its evil consequences do not terminate in the present life, but shall be continued in the world to come; and show him at the same time a practicable method of escaping these evils, and it is impossible to doubt that he will readily embrace it. Men continue the slaves of sin, only because they do not see its enormity, or because they reckon their emancipation hopeless. We conceive that moral reasoning may be highly useful in enlightening the mind with regard to the first of these errors. It is more peculiarly the business of religion to remove the second; and although it does not fall within the province of this article to dwell particularly on the sanctions of religion, yet, as we think that they are most powerfully enforced by the judicious application of moral reasoning, we shall be happy if our speculations can in any degree be made subservient to this important end.

After the general view which has been given, we proceed to consider more particularly the various principles which impel the mind to action, or which influence its determinations; and in this investigation we shall necessarily be called to attend to the *moral estimate* of the actions which result from these principles.

We have seen, that though an invariable rule is pointed out by the constitution of our nature, and the arrangements of providence, yet there is no principle in our nature which directs us to the invariable observance of this rule. If there were such a principle which inclined us irresistibly to the performance of duty, we should cease to be moral agents, and accountable beings. The very idea of a moral action implies that there is a choice between motives, and the greater the struggle, the more glorious is the victory when good principles prevail. There is even among the lower animals a sort of balancing of motives arising from experience and education. A lion, for example, has always a disposition to eat a man when he is hungry; in situations, however, where he has an opportunity of being acquainted with the power and resources of man, he rather wishes to avoid him; and we have heard of a single Moor putting a lion to flight with a stick. The natural propensities of the animal are, in this instance, repressed by fear; and he, no doubt, reckons the risk more than sufficient to counterbalance the expected advantage. A dog has a natural propensity to worry a cat; but a few whippings will restrain him, and teach him to live with the animal, for which he seems to have a natural antipathy, on amicable terms. But this species of discipline does not, in the smallest degree, approach to moral culture. Punishment is associated with the action, and this induces a fear of committing it; but we have no grounds whatever to suppose, that the animal can see any thing like moral impropriety in the action; or that that there is any thing resembling conscience to restrain him.

We grant that there is just as little moral worth in human conduct, when it is disciplined solely by fear, or any other principle distinct from the perception and love of virtue. No action proceeding from any other source can ever be the object of moral approbation; and this forces us again to refer to the will of God as the great standard of moral action, and to the idea of our accountableness to him, as the grand sanction by which moral obligation is enforced; for we hold it to be utterly impossible to perceive the beauty and obligation of virtue, without perceiving that the Being who has established this fair order of things is entitled to our obedience, and that we must be accountable to him for our actions.

Of the simple principles which impel the mind to action, the first which demands our attention is *instinct;* which directs to certain actions, antecedently to all experience, and, probably, in most cases, without any knowledge of the end to be produced. The term is, in general, not used with sufficient precision. It is often confounded with our natural appetites and desires. We would distinguish them in this way, that the appetites are certain feelings of want; whilst *instinct* is the principle which directs to the means of their gratification. Thus hunger and thirst in a child, are not instincts; but suction and deglutition are. This distinction, however, is seldom rigorously attended to. Nothing can be more unphilosophical than the theory which supposes the human mind to be merely a bundle of instincts; and which endeavours to account for the superiority of man, by assigning him a particular instinct adapted to all the emergencies of his circumstances. In this notion, there is a complete confusion both of language and ideas; for if we consider instinct as the principle which, prior to experience, directs with invariable certainty to the gratification of our wants, it is evident that man is of all other creatures the least indebted to this principle for the comforts which he enjoys, and for the feelings which exalt his nature.

In order to understand this subject more thoroughly, let us consider the operation of pure instinct in the case of the lower animals, who are guided by it to all the ends for which Providence has designed them. With them, instinct is all in all. They are directed instinctively to the food which is most proper for them; they construct their nests or their habitations without the aid of a teacher; and no one ever thinks of deviating from the general form adopted by the species. The young are soon as accomplished as their parents; and the only acquisition which they gain by experience, is some knowledge of the enemies whom they have most reason to dread. This they have not by instinct; for we see the young birds, after they are fairly fledged, and capable of flying, yet allowing themselves to be approached by boys, whom, however, they soon learn to consider as their greatest enemies. In some of the South Sea islands, which have been seldom visited, the larger species of *phocæ*, as well as several kinds of aquatic birds, are perfectly fearless; experience will soon teach them to lay aside their confidence in man. This may seem to make some approach to human reason; but it is merely an exertion of memory which they possess in a considerable degree; and without which they could neither avoid the dangers to which they are exposed, nor be susceptible of that degree of education which renders them subservient to the use of man. Their acquirements, however, seem to be entirely accidental, and to depend solely on the simplest modification of memory; a faculty necessary for their existence; for it is by this that the mother must know her young; it is by this that the beasts of the forest know their accustomed lair; and it is by this that they learn to know the places most favourable for prey, and the seasons best adapted for its capture. A wild beast attempting to ford a stream where he has been carried down, and his life endangered, will not try it at the same place again. In these instances, the lower animals are guided by memory, and not by instinct; and memory to this extent is absolutely necessary for the preservation of their existence. To the same source we must ascribe all the attainments of the elephant, in so far as they are not instinctive, and all the tricks which the more sagacious animals learn in consequence of a species of education.

We believe this to be the only encroachment which the lower animals ever have made, or ever can make, on the province of human reason. The comparison of two ideas in the memory, and the perception of their relation, constitute the first link in a process of reasoning; but even this simplest of all intellectual operations, the brutes seldom, or perhaps never employ. Whilst the infallibility of their instincts, and the liberality of heaven leave them nothing to desire, they cut off the possibility of ulterior improvement. They have no need to labour for clothing; it is abundantly supplied by nature; *they sow not, neither do they reap, nor gather into barns; because their heavenly father feedeth them;* they seek no defensive armour; they fabricate no offensive weapons, because nature has amply supplied them with both. They have no need even to tax their memory, as to the food most convenient for them; for here, instinct is their guide, and tells them at once what is most proper and most agreeable.

For what purpose, then, should the inferior animals be possessed of reasoning powers? They never could be called to exercise them; for they gain their object with certainty without them; man himself would not exercise his reason, were he not stimulated by his wants, and destitute of any instinct which might guide him with infallible certainty to the attainment of his wishes. The nature of man is possessed of indefinite capabilities, from the very circumstance of his not having definite instincts adapted to every demand of his desires. In consequence of this defect, he is forced to recollect, to compare, and arrange; and this exercise compels him to discern the beautiful order and wise disposition of the visible creation; and thus to recognise an eternal source of excellence, and an Almighty Being, to whom he owes allegiance, and to whom he perceives he must be accountable far his actions.

But a brute is incapable of any researches; *inopem copia fecit.* Why should he compare, abstract, or generalize? Man does so only from necessity; in the case of the brute, this necessity does not exist; for instinct directs him at once to the object best suited to gratify his desires; and beyond this he cannot form a conception or a wish.

A few instances have been adduced of variable instinct, with a view to prove that human reason is nothing else but instinct capable of indefinite variations. It has been said, and we are not able to contradict it, that certain birds which build their nests among the branches of trees in ordinary circumstances, are accustomed so far to vary their plan, as to form pensile nests, hanging from the branches, in countries infested by monkies. But we have the strongest reason to suspect a variety of species in this instance. It is certain, however, that a monkey exhibits considerable variety of action; and when he cannot crack a nut with his teeth, he takes a stone to assist him. We have also heard that a crow has been known to take a shell-fish up into the air, and drop it among rocks, in order to obtain the meat within. These instances, in so far as they are well authenticated, evidently advance a step beyond the precincts of instinct. In the case of the monkey, however, it may have proceeded from imitation, for a monkey is the most imitative of animals; and if he had ever seen a human being have recourse to such an expedient, it would be readily imitated. Besides, the hands of a monkey are such important organs, and so constantly employed, that such a discovery as cracking a nut by mechanical means, must have occurred; and if it occurred once, it would be remembered. In the case of the crow, also, it might naturally happen, that she would accidentally drop a shell, and descending to recover it, she might find it broken, and the meat accessible; and we see no reason to doubt that the experiment might be repeated, on the same principle as an animal will repair a second time to the place which has yielded him the most agreeable food. We can see little more semblance of reasoning in the case of the crow, than there would be in that of a horse, who, having strayed accidentally into a field affording comfortable pasture, should repair to it again next day, and should seek out the very gap through which he had accidentally gained admission. There is nothing in all this but a simple exercise of memory, without which animals could not exist or be rendered subservient to the use of man. Had they no power of locomotion, so as never to be put in the way of danger, or did every place afford subsistence, and other gratifications, with equal facility, in that case, even memory would not be necessary; and being unnecessary, it would not be imparted, for nature bestows no superfluous gifts; but needing it, as they obviously do, for their preservation and their comfort, it is bountifully conferred; and being modified by the different habits of different animals, it exhibits many singular and surprising phenomena.

This much, then, we allow to the lower animals; and we cannot but be filled with astonishment, when we see them unconsciously accomplishing works which reason can scarcely comprehend, and which require the acutest researches of man to discern the important purposes indicated by their structures and their plans. We are forced to subscribe to the maxim, *Deus est brutorum anima*, in so far, at least, as to perceive that the wisdom and goodness of the Almighty Parent are most distinctly displayed in the unconscious instinctive operations of the lower creatures.

Instinct goes a very short way in regulating human conduct: it is useful to man, chiefly as regulating the functions necessary to vitality; but in so far as his conduct is guided by instinct, he is a necessary, and not a moral agent. To make man accountable, it is necessary that good and evil should be set before him, and that he should have the liberty of choosing between them. The choice is often difficult; because inclination draws one way, and reason and conscience another; and our strongest feelings are frequently opposed to the most obvious calculations of prudence and duty. Moral virtue consists in a man's preferring the latter; for it is then that he gains a victory over himself, and resists the propensities that would lead him astray. The lower animals are altogether incapable of forming such conclusions, or of being influenced by such motives. The prospect of immediate punishment may teach them to repress certain propensities; but they cannot perceive this to be right. On the contrary, there can be no doubt that they grumble at the necessity which compels them. But the human mind recognises a law whose excellence it acknowledges; and the human heart never feels such genuine satisfaction as when it sacrifices an evil propensity at the shrine of virtue and of wisdom.

Instinct directs the lower animals not only to the proper objects of gratification, but to the proper measure and degree of enjoyment. It performs no such decided functions in the economy of human life; for even when we know the objects of gratification, we are under constant temptations to indulge in excess, either of desires or of enjoyment; and by this means we never fail to bring misery on ourselves and others. From this source proceed all the moral evils which deform human nature, and overwhelm the world with misery and crimes. And yet it is the presence and pressure of these evils that afford an opportunity of exercising the most exalted virtues, and of advancing the moral dignity of man. It is from our being made capable of knowing good and evil, that we learn to appreciate virtue; that we recognise an eternal source of excellence; that we see the extent of moral obligation, and perceive that the destinies of our nature point to something more exalted than the gratifications of sense, or the enjoyments of the present world.

Man could not be a moral agent, if he could not do wrong: his obedience in that case would not be more valuable than that which proceeds from the instinctive impulses of the lower animals. In his state of absolute innocence, when there was nothing to seduce, when the passions were in absolute subjection, and the will had no disposition to stray; with all these advantages, he could not have been a moral agent, if he had not had an opportunity of doing wrong. Accordingly, we learn from the short but interesting account of the original state of man given in the sacred Scriptures, (an account which appears to be perfectly consistent with the soundest philosophical opinions,) that such an opportunity was afforded him. An *arbitrary* command was imposed; a *moral* restraint, in a state of perfect innocence, would have been absurd and unintelligible; but he could easily understand the impropriety of violating a positive command, which he felt he had the power to observe or to disobey. Yet still we may have some difficulty in perceiving how he should have had an inclination, in his state of innocence, to break through such a slight restraint. An evil agent is therefore introduced, who suggests temptations and inducements to sin; and he appears to be no superfluous personage in this fatal drama; for though man could have no excuse for yielding, yet he appears a fitter object of mercy, since he was seduced by the artful insinuations of another. We do not know how far we are entitled to lament this catastrophe. Without it human nature would not have been what it is: and as it is, we believe it displays the wisdom and goodness of God more fully than would have been done, had man never gone astray. But we must repress all farther speculations on this subject: if they may be indulged at all, they fall more properly under another department of this work.

It is only during the first stage human of life, that the operations of instincts are particularly observable in man: they seem afterwards to merge so completely in reason and experience, that their influence is little noticed. Hunger, thirst, and the sexual appetite, form another important class of active principles; they are common to man with the lower creatures, and are absolutely necessary for the preservation and continuance of animal life. The immediate object of these feelings is bodily gratification. They originate in the body; they terminate in the body; and are attended with uneasiness till the means of gratification are procured. They are in their own nature perfectly indifferent as to virtue or vice, but they are productive of most important moral consequences, from the pursuits to which they stimulate, from the feelings which they inspire, from the knowledge which they are the means of acquiring, or from the temperance and self-denial which they afford an opportunity of exercising.

There is a remarkable difference between man and the lower animals, with regard to the nature of the food on which they subsist. The various tribes of animals have each a particular species of food appropriated to them. This is so very observable, that it affords grounds for their classification, under the various heads of Carnivorous, Frugivorous, Granivorous, Insectivorous, &c. &c. But man is Omnivorous: he eats every thing that is eatable. This is a beneficent provision of the Universal Parent, in favour of his rational offspring; for it affords them an opportunity of multiplying, far beyond any animals of the same size, who depend solely on one species of food. Man lays every department of nature under contribution; and is thus enabled to promote the multiplication and comfort of his species, without trenching materially, if at all, on the numbers or enjoyments of the lower creatures. There is indeed every reason to believe, that the lower animals, under the dominion of man, are more numerous and more comfortable than they could have been, had they had the world wholly to themselves.

But this is not the only advantage arising from the universal voracity of man. He is perhaps not directed instinctively to any species of food but his mother's milk; beyond this all is the result of labour and experiment. He is forced to observe the qualities of the different articles of food; he thus becomes acquainted with their medicinal properties, and with their comparative value as means of subsistence. Those kinds which he finds most serviceable, he cultivates with care: this brings him acquainted with the properties of the soil, and the various operations of agriculture; and thus, whilst he seems to be solely intent on satisfying the importunate calls of hunger, he is insensibly storing his mind with varied and extensive knowledge.

And there are still more important results arising from that law which gives to man for food, "every herb bearing seed, and every tree bearing fruit, and every moving thing that liveth." Being compelled to seek what suits him best, when once he has discovered it by his ingenuity or by his labour, he concludes with the most perfect conviction that he has a right to the fruits of his discovery. Hence the distinction of property; a distinction which could not exist were no labour necessary, and did the earth produce spontaneously sufficient food to satisfy the appetite of hunger.

On the distinction of property depend many of the relative duties of life, and the greater part of the political virtues. Indeed, the maxim of *suum cuique* embraces almost all the duties which we owe to society. Thus our very wants tend to promote not only our intellectual attainments, but to advance the moral dignity of our nature. Does any one sigh for the return of the golden age, when the earth produced spontaneously all that was necessary for the life of man? Such a change would be in the highest degree pernicious, unless the nature of man were altered with the nature of things; and vice and misery banished from the face of the earth. The present state of things is exactly accommodated to the present circumstances of human nature. Our very virtues would perish, were things different from what they are. Were men rendered independent of each other, by the too bountiful provision of nature, there would be no room for the tender charities of sympathy, benevolence, and mutual assistance. In the present state of human nature, it is necessary for our improvement, that we should "eat our bread with the sweat of our brow."

The appetite of thirst also gives rise to some singular consequences, which have a very considerable effect on our moral feelings. Water is the natural beverage to which instinct directs every animal, when deprived of its mother's milk; and thirst, when not gratified, becomes the most excruciating torment. As men, in many situations, could not readily command a supply from springs, or running streams, they would naturally look out for a substitute: this they would find in the juice of fruits and succulent herbs. In attempting to preserve this as long as possible, they would find a singular change produced by fermentation; a change which made the liquor keep much longer, whilst it communicated to it new and pleasant qualities. A field is thus opened up for a new species of industry and ingenuity; and also for the exercise of a new set of moral qualities: for these newly invented liquors intoxicate, whilst they exhilarate, and remove mental depression at the risk of intemperate excesses. It would soon, however, be found, that excessive excitement either gave birth to immoral practices, which cool reason condemned, or was succeeded by a corresponding depression, which more than counterbalanced the preceding elevation. This would tend to teach moderation, and would afford another opportunity of learning those lessons of temperance and self-denial, which are alike essential to virtue and to happiness.

The sexual appetite gives birth to many important consequences, moral, physical and political. It is wisely ordered, by the Author of our nature, that this feeling does not begin to operate till reason can, in some measure, control its excesses, and till man is enabled, by his own labour, to support his offspring. Were it to operate sooner, there would be an excess of population, without the means of subsistence; and the mind and body would be alike enervated, and unfitted for the attainment of those useful qualities which are necessary for the business of life. In man this appetite gives birth to love, with all its tender associations and endearments; a passion totally unknown to the lower animals, in its more refined sense, but which, in the human species, stimulates the mind to the most noble exertions, or enriches it with the most amiable feelings, or soothes it by the most pleasing hopes.

This appetite, in the lower animals, is gross and evanescent, being easily satiated with periodical gratification. In man, the attachment being founded on mutual esteem, and valuable mental endowments, and the stimulus being not periodical but permanent, the connexion between the sexes is, in its very nature, calculated to be lasting; and hence arises the permanent connexion of marriage, which, in almost every country, is considered as indissoluble, except by the death of one of the parties.

But besides this there is another reason, founded in the very constitution of human nature, why the marriage contract should be indissoluble. For who is to support the offspring, during their long immaturity, if the connection between the parents be dissolved? Promiscuous concubinage would soon dissolve all the charities of life, and undermine the pillars of society. But marriage keeps alive the parental feeling, by keeping the child in the presence of its parents; and this again strengthens the attachment between husband and wife, by placing before their view the pledges of their mutual endearments. In the case of the lower animals, the first of the offspring is always independent before another is produced: in the case of man there may be a dozen dependent children at once, in different degrees of helplessness; for additional offspring is produced before the former is independent: and thus a succession of ties strengthen the matrimonial connection; and a thousand feelings are generated in the mean time, which bind man not only to his family, but to his species.

It has been supposed by some that there is a congregating propensity in man, as among other gregarious animals; and that he is driven instinctively to desire the society of his species. Others again suppose him to be completely anti-social, and that he is induced to seek the fellowship of his species, merely as the means of defence against animals more powerful than himself.—Whenever we find two opinions on the same subject diametrically opposite to each other, we have reason to conclude that neither of them is exactly true; or, at least, that they have not been stated with sufficient explanation or qualifications.

We do not think it possible to prove that there is in man a principle similar to that which operates in gregarious animals, in making them desire the society of their species. There is, indeed, in man a strong social propensity, which results necessarily from the constitution of his nature, but is not, we believe, an ultimate principle. Suppose the whole human race to have sprung from one pair, and give to this pair a more than ordinary degree of longevity; and you see at once a complete system of society, and the origin of civil polity, arising out of the conjugal connection, consolidated by parental and filial ties, and gradually extending its ramifications till a tribe or nation is constituted, acknowledging a common principle of association, and tracing its origin to the same head.

In this view of the subject there is a necessary, but not an instinctive principle of association; and society will be found to be held together by rational, yet unavoidable ties, since our natures are so constituted, and our circumstances so disposed, that we cannot but feel their obligation.

The opinion which supposes men to have associated merely from the conviction of their own helplessness, is still more untenable than that which ascribes their association to a gregarious instinct. This conviction may be a very good additional reason to keep them together, but it never was the principle on which any society was originally formed. Man is born in society, and trained to the love of society by numberless powerful associations: it is only in society that his powers can be evolved, and his faculties called into exercise: we may therefore conclude, with certainty, that this is the state for which he was intended by the author of his nature, and that the social system is not the result of accident, but of infinite goodness and unerring wisdom.

When society is widely extended, common laws and common religious principles are brought in aid of the natural bonds of union, which are apt to be lost sight of in the midst of complicated political connections. In such a state men scarcely look beyond the artificial regulations which apply to their immediate conduct, and are apt to think that society is a work of human invention, arranged and methodized by the wisdom of some political sages. The hand of man may, indeed, be seen in every well regulated society; but it is only to give strength and efficiency to those great natural principles which have their origin in the contracted sphere of family connection. All artificial and political regulations depend on these principles, and derive their obligatory sanctions from them; in the same manner as artificial signs in language derive their power and significancy from those which are natural. "There is such a natural principle of attraction in man towards man," says Butler, "that having trod the same tract of land, having breathed in the same climate, barely having been born in the same artificial district or division, becomes the occasion of contracting acquaintances and familiarities many years after; for any thing may serve the purpose. Thus, relations merely nominal are sought and invented, not by governors, but by the lowest of the people, which are found sufficient to hold mankind together in little fraternities and co-partnerships: weak ties, indeed, and what may afford fund enough for ridicule, if they are absurdly considered as the real principles of that union: but they are, in truth, merely the occasions upon which our nature carries us on, according to its own previous bent and bias; which occasions, therefore, would be nothing at all, were there not this prior disposition and bias of nature."

Besides the instincts and appetites common to man with the brute creation, and which are absolutely necessary for the preservation and continuance of the species, we are conscious of desires of a more dignified nature, which raise man far above the lower animals, and carry him forward in the career of indefinite improvement. We do not think that the number of these desires can be distinctly specified. Dr. Reid has mentioned the *Desire of Power*, the *Desire of Esteem*, and the *Desire of Knowledge;* to which Mr. Stewart has added the *Desire of Society* and the *Desire of Superiority;* and we see nothing to hinder others from extending the enumeration. These philosophers consider the desires which they have specified as ultimate and instinctive principles of our nature: to this we cannot assent, without altering the usual acceptation of language. We have already said that we do not consider the desire of society as an instinctive principle, but as arising necessarily out of the ordinary circumstances of human nature. That which is instinctive cannot be counteracted. But we conceive it perfectly possible for a mother to fly from society, to train her child in solitude, and teach him the arts of savage independent man; and we think there is every probability that a child thus trained would grow up in fear and hatred of his own species, till perhaps the sexual appetite drove him to desire a more intimate acquaintance with them. But, man born in society, and growing up amidst the extending ties which strengthen the social union, is led, both by education and habit, and feelings, to desire the company of his species.

The *desire of knowledge* is generated in the progress of society, but we do not desire it till we find that we cannot do without it, and the majority of mankind are satisfied with a very moderate portion. When the savage has knowledge sufficient to manage his weapons, or to match his enemy in stratagem, he feels no violent *orexis* impelling him to farther acquisitions. We do not, therefore, regard the *desire of knowledge* as an instinctive principle: we consider it rather as a rational desire, recommended by its perceived utility; for though a certain degree of knowledge is necessary in every stage of society, and is, in fact, unavoidably acquired by our intercourse with material objects, and by the results of experience, yet the desire of knowledge, for the sake of knowledge, operates only in an advanced state of human improvement.

That the *desire of power* is a natural and universal principle of our constitution cannot be denied; nevertheless, we conceive it to be unphilosophical to consider it as original and ultimate. It is quite evident that man feels himself in want of many things; and nothing can be so welcome to him as the means of procuring them. On this is founded the desire of power, the only object of which is to supply the wants and desires of our nature. This desire of power, then, as it has been called, is nothing more than a desire to have the means of procuring the enjoyments which we think necessary for happiness; and hence it is manifested in a great variety of ways, according to the views which men have formed of enjoyment. If knowledge appears the most likely means of advancing our character, or of securing any desired pleasure, we eagerly seek knowledge. In this case, those who have never heard of the name of Bacon act under the influence of his maxim, that *knowledge is power*. If sensual indulgence be the prominent desire, the means of gratification are sought with no less keenness; and hence the desire of riches is generated, as these seem to be the most convertible means for procuring varied enjoyments.

But, in the progress of mental improvement, some may perceive that a man's happiness consists as much in the limitation of his desires as in the extent of his gratifications; hence, they seek their security in self-control and in the government of their passions, adopting as a maxim, *Non desiderare jucundius est quam frui.* These persons, as Cicero observes, are animated by the same principles which impel to the most arduous enterprise of ambition, the object of both being *Ne qua re egerent.*

Such principles as these, however, can only operate in a considerably advanced state of mental refinement. In the first instance, the appetites are clamorous, and it is the first desire of every man to gratify them in the way which they seem to point out. This gives rise to a thousand varied exertions, and to numberless experiments and disappointments, which often produce much misery both to the individual and to society. But the result, upon the whole, is salutary; the stock of knowledge is increased, the moral discipline of the species is promoted, and a wise man will recognise an overruling Providence, when he sees the general order of the world maintained inviolate, amidst the confusion of human passions.

If any one of our desires could be entitled to rank as an ultimate principle in our nature, we should think the *desire of esteem*, or of being loved, might claim that distinction. It operates powerfully and universally, and yet it is easy to see how it is generated in the infant mind by the caresses of the parent and the advantages which accompany them. The child perceives that his happiness depends on the good will of his parents, and therefore it is impossible for him not to desire it. The feeling expands with advancing years, and, as we are formed to be dependent on each other's exertions, we perceive that we cannot be independent of each other's esteem. Let it not, however, be supposed, that we consider the desire of esteem as factitious or accidental. We admit it to be a natural, universal principle of our constitution, as much so, indeed, as the ideas of *right* and *wrong*, *virtue* and *vice*, which, though not innate or instinctive, are nevertheless forced upon us by the condition of our nature, and by the circumstances in which we are placed.

There are some philosophers who seem to think that we detract from the dignity of human nature, unless we allow to man a set of original instincts and feelings, totally distinct from those of the lower animals. We, on the contrary, think that it is most for the honour of man to make him almost wholly a *rational* being; for, in proportion as he is guided by instinct, he is a necessary agent; it is only as a rational being, capable of weighing motives, that he can be the subject of moral discipline, or responsible for his actions. Others, again, think it derogatory to the honour of the Creator, to allow any influence to man in the fabrication of his fortune, or the formation of his character. All that we contend for is, that though God has established immutable laws, which no effort of man can alter, yet we are permitted to resist them so far as to create a temporary confusion, or local derangement, or even to ruin our own happiness, whilst yet the general order of things remains perfectly unaffected by our madness.

Mr. Stewart distinguishes between the appetites and desires, by saying that the latter are not occasional like the appetites, nor do they, like them, take their rise from the body. Our desires are, no doubt, some degrees removed from the grosser elements of appetite, but no small number of them originates in the ordinary appetites of our nature, and there, too, with the bulk of mankind, they terminate. Others of them originate in our bodily senses, and have for their object the gratification of feelings immediately connected with these senses.

We believe that Mr. Stewart, who seldom errs but on the side of excessive caution, was afraid lest some dangerous consequences should be deduced, from referring the origin of our desires to the appetites and senses. For, as Locke's Theory of Perception has been adopted by materialists, who maintain, that if all our knowledge be by sensation and reflection, there never can be any thing in the mind but the ideas of sensible objects, so it might be said, that if our desires originate in the appetites and senses, the gratification of these must constitute the ultimate and legitimate object of human enjoyment. But as Mr. Stewart has qualified Locke's doctrine, by saying, that though certain kinds of knowledge cannot be referred immediately either to sensation or reflection, yet these principles furnish the occasions of acquiring all our knowledge, so he might have said, that the appetites and senses furnish the occasions of exciting the various desires which actuate human nature. Not that we would absolutely assent to this doctrine, though it is evident that it must be very generally applicable.

We have already said, that the feeling of want creates the desire of power; and knowledge, riches, honours, public applause, &c., are only modifications of power, or means of procuring what we desire. We might conceive the desire of these things, therefore, to originate in the bodily appetites, as these give rise to the pressing wants of our nature. But, besides this, an extensive class of desires has its origin in the gratifications required by the different senses. The eye, the ear, the taste, the smell, and, in a smaller degree, the touch, have each their specific gratifications; and, hence, there is room for indefinite, or almost infinite, objects of desire. The ear gives rise to the pleasures of harmony, it enables us to appreciate the pathos of poetry and of eloquence, and all the delights of human converse: the eye gives rise to painting, statuary, architecture, and all the imitative arts.

From the same source are derived our conceptions of grandeur and sublimity in the works of nature, and also those ideas of proportion and relation which give rise to the mathematical sciences. The taste, and the smell, do not give birth to any intellectual ideas, but they suggest numberless objects of desire, to stimulate the activity of rational beings, and thus to put them in the way of acquiring knowledge, when they are only seeking sensual gratification.

But though it is quite evident that a very numerous class of our desires must be referred immediately to the body, as they have for their object the gratification of the appetites or the senses, yet we admit most readily, that what may be called the moral desires of our nature, must have a different origin. The desires connected with the senses, though they lead to the most extensive knowledge, and to the most elegant and wonderful attainments, yet do not constitute a single element of moral feeling. They may, indeed, be rendered highly subservient to morals, as means, or instruments; for extended knowledge should make us better acquainted with the laws, and the Lawgiver of the universe. But, in themselves, they are wholly indifferent as to virtue or vice; they may be converted to either, according as they are improved or perverted, and a man who is an adept in all the attainments of science, or of art, and nothing more, is yet a stranger to the noblest feelings, and best hopes of our nature.

We are, indeed, firmly persuaded, that nothing but the idea of God, and the conviction of our accountableness to him, can raise us above the importunities of appetite and the gratifications of the senses, or teach us to delight in feelings and contemplations, of which, without this idea and conviction, we never could have formed a conception. These impressions respecting the government of God, do not originate in the senses, yet they are not foreign to human nature. We have shown elsewhere, that the idea of power originates in our own conscious energies; (see Logic) after this, one link only is necessary to connect our thoughts with God, and we are compelled to admit his existence, his power, and his government, as soon as we perceive that the power of man could not make or sustain the universe. Our ideas of God, acquired in this way, will, indeed, be very imperfect; but they exhibit the elements of that more perfect science which revelation has made known.

It is here, then, that our moral character commences, for we now recognise our obligations to obey the laws of the supreme Lawgiver, and perceive it to be our paramount duty to seek to know his nature and his will. In this investigation we must soon discover, that he is totally free from the solicitations of sense and appetite, that his goodness flows unconstrained, and untainted by selfish feelings, to every thing that lives. We see it to be our duty to imitate him, and perceive the resemblance to be more complete, in proportion as we emancipate our minds from sensual gratifications, and raise them to the contemplation and love of that excellence which is inherent in the nature of the God whom we worship. It is then that we perceive a pure and adequate motive for the practice of the sublimest virtues, for we see that they are necessary to constitute our resemblance to the Parent of the universe, without which we cannot expect to be the objects of his love.

It is true, indeed, that men are trained to the duties of moral agents by the laws and institutions of the country in which they live. But these can only produce external conformity; the principle of obedience is founded in a recognition of the wisdom of the divine law, and in an admiration of the excellence of the divine nature. When the laws of men correspond with what we see so conspicuously displayed in the arrangements of Providence, they have the force of a divine sanction; when they have a contrary tendency, we pronounce them to be injudicious and oppressive, though fear may enforce a reluctant submission.

Human laws, then, borrow their influence, and derive their sanction from their conformity to the visible arrangements of heaven, and without connecting them with these as their foundation, they never can train the mind to moral feelings, nor inspire a love of the *pulchrum et honestum*, abstracted from temporal advantages. The conscience, indeed, may acquire a sort of artificial influence, from circumstances of education and early associations. But it is then little better than a prejudice, useful, no doubt, to the general interests of society, but not yet exalted to the dignity of a moral principle.

A well-informed conscience is unquestionably the best safeguard to virtue; a conscience under the influence of superstition or ignorant prejudice, is the most powerful instrument of mischief; a timid or a ticklish conscience will render the life miserable, and the conduct vacillating and uncertain. Thus, though conscience pronounces decisively on the subjects which come under its cognizance, yet another principle is necessary to determine whether its decisions be correct. On this account we have considered it, (see CONSCIENCE) only as a particular modification of the principle of moral approbation or disapprobation, directed solely to the examination of our own feelings and conduct, and increasing in an astonishing degree our happiness or misery, according as it leads us to approve or condemn our own actions. When its intimations coincide with that *amour propre*, which is natural to every human being, it enhances our happiness in the highest possible degree, as we then feel as if we had some good grounds for that self-partiality which we are so much inclined to indulge. But when, on the other hand, it pronounces our condemnation, it sinks us in our own esteem, and thus infuses a feeling of misery, such as all the opposition and reproaches of the world will not produce, whilst we stand well with our own consciences.

The principle of conscience, then, we conceive, derives its influence, not from being possessed of any independent, autocratical power, but from a conviction that we are continually in the presence of God, and must be accountable to him for our actions. This is unquestionably the ultimate and only safe foundation of its operations: and, therefore, we conceive it to be legitimate reasoning to infer the being of a God from the operations of conscience, as we do not see any rational grounds for them apart from this consideration. The ancient moralists, indeed, like many among the moderns, held conscience to be an ultimate, and not an inferential principle, and have given us most beautiful illustrations of its power over the mind of man. There is not, perhaps, to be found in any language a more powerful description of its effects, than occurs in the thirteenth satire of Juvenal: yet he never once alludes either to the belief of a God, or of a future state, as lending to conscience its chief sanction and authority. This is quite consistent with the view which he took of the independent power of conscience: and we have no doubt that it does frequently operate most powerfully, without referring immediately to such considerations: But we have as little doubt, that when its operations come to be analysed, the terrors and strong emotions which it produces will appear to be only superstitious bugbears and idle prejudices, if we separate it from the belief of a God, and a state of retribution.

Besides our appetites, which are necessary for the preservation of life, and the continuation of the species, and the various desires which take their rise from them, or from the bodily senses; we are conscious of other feelings, which have been called affections, and which are supposed to be distinguished from the appetites and desires by this circumstance, that our fellow-creatures are always the objects of them. They are called benevolent or malevolent affections, according as we feel a desire to promote or obstruct the happiness of others.

As there are certain objects which offend or gratify the external senses, so there are certain exhibitions of conduct and feelings peculiarly offensive to our moral perceptions, and which produce a sensation of dislike or abhorrence infinitely stronger than can arise from any affection of the senses. We believe this to be the origin of the *malevolent affections*, although this moral dislike and aversion does not absolutely amount to malevolence, as it is possible to feel such dislike, without hostility to the person who excites it. It is seldom, however, that this is the case; and the dislike which we feel towards moral agents most commonly produces in our minds hatred, and the whole train of malevolent affections.

Perhaps none of our natural feelings are *directly* malevolent. Anger is undoubtedly the original feeling, on which malevolence may be very easily engrafted; but this is not a necessary consequence, otherwise the injunction, *Be angry and sin not*, could never proceed from the religion of peace. Envy, jealousy, and revenge, are *directly* malevolent; but they are superinduced qualities, originating in the perversion or abuse of innocent or indifferent natural feelings. Butler, in his first Sermon on Human Nature, observes, that "as there is no such thing as self-hatred, so neither is there any such thing as ill-will in one man towards another, emulation and resentment being away; whereas, there is plainly benevolence, or good-will: there is no such thing as love of injustice, oppression, treachery, ingratitude; but only eager desires after such and such external goods, which, according to a very ancient observation, the most abandoned would choose to obtain by innocent means, if they were as easy and as effectual to their end."

We do not mean to vindicate human nature from the charge of malevolence; that such a quality exists, is proved by fatal experience; and we presume it will not be difficult to show, that it rises necessarily out of the circumstances of human nature.

Though natural objects may excite our disgust, yet we never view them with malevolent feelings. We do not consider them as objects of blame, because we know that they are not answerable for the offensive qualities which they possess. There is no volition in the injury which they inflict, and there is no *malus animus* towards the sufferer: it is this which constitutes the essence of an offence, and where this is wanting, however much we may be injured, reason says that we ought not to be offended. We view the hostility of a tiger with nearly the same feelings; we consider his rage as indiscriminate; and though we fly from him with terror, yet we do not view him with malevolence. If a dog, however, or other animal, should single out an individual, and, direct all its fury against him, whilst it is courteous to every other person, that individual could not avoid feelings of irritation, hatred, and malevolence: he would regard the animal as a personal enemy, and would rejoice in its destruction.

This is nearly the form which malevolence assumes when directed towards a human being; and, from the circumstances and constitution of our nature, we believe it to be impossible to avoid every degree of this feeling. It is impossible not to dislike those who have injured us without provocation. But this feeling of dislike does not amount to a moral offence. We may even go farther than this without offence to good morals; for when we see a person anxiously seeking opportunities of hurting us, and employing his power, wealth, and influence, to accomplish our ruin, we conceive that we may rejoice without blame, when his power, wealth, influence, and every means of annoyance which he employed against us, are destroyed. We cannot but feel *ill-affected* towards such a person; yet we are not guilty of malevolence, considered in the light of a moral offence, unless we feel a rancorous and excessive desire for the destruction of our enemy.

Our dislike of objects naturally offensive or dangerous never amounts to hatred: we only seek to avoid them; and, therefore, carefully shun the situations where they are likely to be found. But when we have enemies in human shape, and in human society, this cannot be done; we can only fortify ourselves against their arts by counteraction; and we are compelled to seek our own security by exposing the malignity, hypocrisy, and worthlessness of our enemies. This has all the appearance of malevolence; and, in general, it soon actually becomes so: for as love begets love, so there are few minds in which hatred does not produce hatred, and offence the desire of revenge.

It has often been observed, that the malevolent passions are always accompanied with painful feelings to those who indulge them. This has been considered as a wise arrangement of Providence, to impose a restraint on qualities so obviously injurious to the peace and happiness of society. The argument is not weakened by showing that melevolence must necessarily be accompanied with pain, if the account which we have given of its origin be correct: for it evidently originates in *fear* or in *dislike;* and whilst these qualities are present to the mind, it would be as impossible to feel comfortable, as it would be to remain perfectly undisturbed in the presence of a wild beast which we fear, or in the midst of noxious and offensive objects, which our souls abhor.

Whilst, then, we admit that there is a vast deal of malevolence in the world, yet we think that it is not so much a native principle, as the corruption and abuse of feelings naturally indifferent, and capable of being applied to very different ends. At the same time, we do not imagine that there is the slightest chance that this perversion can be avoided. We have the highest authority for stating that *offences must come:* they are often unintentional on the part of the offender; they may arise from his ignorance of our feelings, our characters, or our circumstances. We, on our part, are perhaps equally ignorant of his feelings and intentions: we are, therefore, always apt to confound injury with injustice, and to ascribe the evils which we suffer to bad motives, on the part of him who is the cause of them; and we believe it to be impossible, in the ordinary circumstances of human nature, not to feel ill-affected towards those who have caused us pain and suffering. Opposite feelings may indeed be implanted, and high Christain principles may teach a man to love his enemies, and to do good to them that hate him. But the ordinary feeling of human nature is, to hate them who hate us,

——Vindicta bonum vita jucundis ispa.

The heathen moralists were not agreed on this subject. Some of them considered revenge not only as allowable, but praiseworthy. Of this number are Aristotle and Cicero. The former says, that it is the property of a slave to put up with an injury. (Ad Nicom. iv. 11.) And Cicero glories in cherishing the feeling of revenge. *Odi hominem et odero, utinam ulcisci possem.* (*Ad Att.*) Some of the ancient moralists, on the other hand, pointedly condemned revenge. (See the authorities collected by Grotius, De Verit. l. iv. c. 12.) It is sufficiently evident, however, that they were not possessed of any principle of sufficient efficacy to enforce the doctrine of forgiveness. Juvenal declaims eloquently against revenge; but his argument is rather satirical than solid: it is because revenge is chiefly the passion of a woman.

——Quippe minuti
Semper et infirmi est animi exiguique voluptas
Ultio. Continuo sic collige, quod vindicta
Nemo magis gaudet quam femina. *Sat.* 13.

Though we have expressed a doubt whether any of our natural feelings be, in the first instance, decidedly malevolent; yet we have pointed out a fertile source from which malevolent affections may, and in the ordinary circumstances of our nature, must proceed. For the purposes of *parænetical* exhortation, it may be most useful to take the passions in their matured state, and, without attempting to trace their origin, to point out their consequences. But as our object is analysis, rather than moral suasion, we have all along deemed it necessary to mount as far as possible to first principles, and to show the steps through which the feelings pass, till they reach their decided character of virtuous or vicious habits or affections. It is the same thing as to the practical result, whether malevolence be considered as an original feeling, or as resulting necessarily from the circumstances in which we are placed: but it is not the same thing as to arrangement; that being always the best which approaches nearest to elementary principles, as it enables us to trace more completely the progress of the vicious affections, and to detect the circumstances which have nourished and matured them.

The benevolent affections are original feelings, flowing immediately from principles implanted in our nature. The benevolent affections enumerated by Dr. Reid, are parental affection, gratitude, pity, esteem of the wise and good, friendship, love, and public spirit: to which Mr. Stewart adds filial affection, and affection of kindred. It is obvious, that, on this plan, the enumeration may be considerably extended; but this would only be tracing the ramifications of one or two original principles, which assume different aspects according to the circumstances in which they are exhibited. It would be to confine our attention to the branches, the foliage, and the fruit, without considering the root by which they are nourished; or the cultivation which is necessary to render them fresh and vigorous.

Of the benevolent affections decidedly original, are love and parental affection; these lead us at once, without reasoning, and without calculation of consequences, to desire the happiness of those who are the objects of them: and we believe, that from these two, most, if not all, the other benevolent affections may be derived.

The love of a parent to his child is irresistible: it is a strong constraining principle, alike imperative on man and the greater portion of the brute creation. Some among the ancients imagined that there was a kind of undefinable feeling which they called στοργη, inclining the hearts of parents and children to each other, though from any accident their features and persons should not have been previously known. This notion now seldom finds a place, except in the dreams of romance. But though the feeling be divested of those mysterious powers, which some, who had more imagination than philosophy, once ascribed to it, it is still sufficiently prominent, and asserts its decided claim as one of the strongest original feelings of our nature.

The parental feeling is powerfully manifested in the lower animals. Every boy must remember how artfully he has been misled by the partridge, the snipe, the lapwing, or the wood-pigeon, when they feigned distress, and exposed themselves to evident danger, for the protection of their young. A hen, proverbial for cowardice, will attack the most formidable mastiff, when he comes too near her brood; and it is curious to observe the intimidating effect of rage, even when devoid of strength: the most powerful animals often shrink from the feeblest assailant, when it is armed with the reckless courage inspired by parental affection. We have seen a sheep fairly beat off a fox who attempted to seize her lamb. And as a farther illustration of the power of parental affection, and of the intimidation or respect which the courageous display of it inspires into the most powerful animals, we may mention a recorded fact which must be familiar to many readers. A lion, who had broke out of a *menagerie* in a town in Italy, seized a child whom he found in the street, and was carrying it off: the mother perceiving the circumstance, threw herself, in a frantic manner, before the lion, and loudly demanded her child. The animal, astonished or terrified, dropped his intended prey, and allowed the distracted mother to carry off her child in safety.

In man, indeed, the parental feeling derives additional force from the principle of association, and a thousand adventitious aids are brought into action, to strengthen and confirm its power. We may, nay, we must become more attatched to our own children than to the children of others, were it for nothing else than the mere frequency of intercourse: and as soon as we see our caresses appreciated, and our anxious desire to please repaid by a smile, an additional bond of endearment is created, and a mutual interchange of love is established.

We wonder that this was not perceived by the accurate Dr. Reid to be sufficient to account for the strong affection which a nurse entertains, even for a child that is not her own. "It is very remarkable," he observes, "that when the office of rearing a child is transferred from the parent to another person, nature seems to transfer the affection along with the office. A wet nurse, or even a dry nurse, has commonly the same affection for her nursling as if she had born it. The fact is so well known, that nothing needs be said to confirm it, and it seems to be the work of nature."* It is indeed the work of nature, acting on the infallible principles of association: but, in its origin, it has nothing akin to parental affection, which is an inborn, not an implanted quality, and which may be strengthened by various associations, though it is not generated by them.

The desire of founding a family, and transmitting a name to posterity, may operate with some as an inducement to pay particular attention to the rearing of their offspring. But these are only secondary considerations; and the feeling operates in full force, where they are unfelt and unknown. For even when the prospect of a family presents nothing but additional burdens, and accumulated cares, yet even then the parental feeling is twined round the heart; and that man would be reckoned little better than a monster, who would hesitate to risk life itself for the safety of his child.

But though this principle can exist in the midst of poverty and misery, it may be weakened, and sometimes wholly obliterated, through the prevalence of luxury, or the love of pleasure. The sanctioned frequency of infanticide among many nations arises from the parents finding their children an obstruction to their individual gratifications. On this principle is founded the society of the Arreoys in the South Sea islands: the society is, or rather was, held in the highest respect, and all who became members of it were bound in the most solemn manner to destroy all their children. An instance is recorded of a member of this society being married to a daughter of one of the kings, by whom he had eight children, who were all murdered in succession, without the slightest imputation of blame. We are happy to record the triumph of Christianity over this most barbarous and inhuman practice.†

It is not only among the ignorant and uninformed votaries of pleasure that this subversion of parental affection has been witnessed: it has often been found to exist to a most disgraceful extent, during periods of the highest intellectual refinement: for nothing is sacred to the love of pleasure; it prostrates every generous affection, and erases from the human heart those characters which were engraven on it by the hand of its Maker. Strong as the parental feeling is, then, we may see the necessity of every accessary aid that can be brought into action, to maintain its influence against the deadening effects of luxury, and the love of indulgence. And Providence, in its wisdom, has furnished such aids. In fashionable life, children are little regarded; and if they sometimes appear less spoiled than the children of the lower orders, it is only because they engage less of the attention of their parents, and thus accidentally escape that injudicious kindness which renders them intractable and disobedient. A fashionable mother cannot submit to the drudgery of nursing her child; and a fashionable father would give himself very little trouble about his instruction, were it not to support the eclat of a name, and to inherit the family for-

* Active Powers, p. 151, 4to.

† Christianity is now (1819) the acknowledged religion of all the islands under the command of Pomare, King of Taheite.

tune and honours. We believe, indeed, that were it not for such considerations as these, there would be few children among the lovers of pleasure to make any demands on parental affection.

Juvenal gives a horrible account of the practices which were adopted in his time, to avoid the incumbrance of a family. His unvarying malignity to the fair sex might render his testimony suspected, were it not borne out by other evidence.

> Sed jacet aurato vix ulla puerpera lecto :
> Tantum artes hujus, tantum medicamina possunt,
> Quæ steriles facit, atque homines in ventre necandos
> Conducit.

But the powerful feeling of parental affection is weakened or destroyed, not only by the prevalence of luxury, or the love of pleasure ; it might also be endangered by the necessitous circumstances of the parents, were there not counteracting considerations to induce the rudest and most wretched tribes to rear and protect their children. Among savage nations, children would be in danger of being neglected, as the love of ease might get the better of parental affection. But this is counteracted by the consideration, that the strength of their family or their tribe is to be advanced by the children whom they rear. And that this consideration is more powerful, in many instances, than parental affection, appears from this, that among savage nations none but healthy and well-formed children ever arrive at maturity : from which we may naturally infer, that the weakly and deformed are either exposed, or allowed to perish through neglect.

Love is an affection decidedly benevolent, as it leads us directly to desire the happiness of the person whom we love. Love cannot exist but between persons of different sexes ; it is therefore evident that the sexual passion is a strong element in its composition. We, indeed, extend the meaning of the term ; and when we feel any strong partiality for a person, arising either from gratitude or from the perception of amiable qualities, we are said to love him : and we believe, in fact, that there cannot be love even between the sexes, unless it be founded on some real or supposed mental excellence. Where love really exists, the desire of enjoyment is always accompanied with esteem of the person beloved : without this it is mere brutal appetite.

Beauty is, perhaps, the principal attraction ; it is often the only one that seems to be recognised. But if we proceed to analyse this magical quality, we shall find that it owes its influence chiefly to the idea that the face is an index of the mind ; and that the perfection of beauty is always supposed to imply the perfection of amiableness in character and disposition. Every heroine of romance is always a paragon of beauty ; and no writer has yet had sufficient confidence in his own powers, to attempt to interest his readers in behalf of an ugly woman. All this proceeds on the idea, that beauty is generally accompanied with some amiable or exalted mental qualifications.

If this is a prejudice, it is at least one that has some foundation in nature : for it cannot be denied that ugliness is generally accompanied with some qualities not particularly amiable. We do not, however, pretend to affirm that this consequence is the necessary result of the mal-conformation of the countenance or person. It may be easily accounted for on other principles. The ugly person may be chagrined by the unkindness of nature. She may feel indignant to see incense paid to beautiful insipidity ; whilst she, with an inferior face, but with vastly superior qualifications, may be scarcely able to command common politeness. Thus, the neglect with which an ugly woman is too generally treated, may sour her temper, and diminish her benevolence : and after she has been driven by the injustice of the world to put herself in a posture of self-defence, or defiance, she is accused of being naturally peevish, envious, and malignant.

We can see no reason why she should be naturally more deficient in amiable qualities than her fairer rivals ; and were she treated with the same respect, we have no doubt that she would show the same amiableness of disposition. And, certainly, a plain-looking woman, perfectly amiable and unenvious, would present a phenomenon of excellence, which, from its rarity, may justly be deemed more dazzling than the most splendid beauty.

But, besides the beauty of external features and form, love is kindled by an indefinite number of qualities which have taken hold on the imagination of the lover, and which he regards as the sure signs of every desirable excellence. These qualities are extremely various, according to the particular views, habits, and feelings of individuals, into which we do not, at present, mean to enter ; and the only object which we have had in view in this discussion respecting the origin of love is, to show that, in the proper acceptation of the word, it cannot exist but with the perception, or supposed existence, of some good mental qualities in the object beloved. The mere animal passion may exist, and be gratified, without this perception or desire of excellence. But rational beings alone are susceptible of love, in the proper acceptation of the term ; and mental qualifications, real or supposed, are always essential ingredients in its composition.

In this view, the affection, or the *passion* of love, (as it is called, when it becomes so powerful as to engross the feelings,) is deserving of the attention of the gravest philosopher, as presenting a most powerful stimulus to action, and inciting to the attainment of many qualities which occupy a prominent place in the character of man. It becomes highly interesting to consider the moral influence of this powerful universal principle on human manners : and the wisest will be found to confess, that it has infinitely more effect than some more rational considerations in humanizing the mind of man, and in training him to many useful endowments.

We have endeavoured to show that mental qualifications constitute the charm of love. The lover, therefore, will naturally seek to be distinguished by the qualities which he may think most likely to recommend him to his mistress. And as it is evident that women stand in need of protection, (being greatly inferior to men in bodily strength, and, at certain periods, totally incapable of defending themselves from surrounding dangers, or even of earning subsistence,) the highest recommendation of man in a rude state of society will be personal bravery, or strength. In a more polished state, he will seek to be distinguished by tenderness, generosity, or sympathy ; and in a state of independence and affluence, by those talents and attainments which secure an influence in society. Thus, in every state of society, the principle of love has a powerful influence in moulding the manners, and forming the character of men.

The operation of the feeling on the other sex is quite reciprocal. The female naturally studies the qualifications most likely to recommend her to the object of her choice; and if at any time her pursuits should be trifling or useless, we may rest assured that her choice has originated in the frivolity of the men—for it is their taste, in every instance, which decides the nature and character of female accomplishments. The woman who wishes to please will not think it necessary that her qualifications should exactly resemble those of the man whom she loves. His strength, and courage, and energy, are required as compensations for her weakness; and, therefore, though she should be deficient in these respects, she will not be the less endeared to the man who glories in being called her protector, and who, without any feelings of selfishness, is glad to be possessed of qualities of which she is destitute, that he may the more decidedly prove the extent of his love.

It is by no means necessary, then, that the pursuits of the man and of the woman should be similar, in order to secure mutual regard. They must indeed be actuated by the same grand moral feelings; there must be the same regard to truth, honour, and principle—the same anxious desire to promote each other's comfort; and after this, it matters not how dissimilar their occupations may be. They will rather injure their interests by attempting an approximation in any other respect: and Hercules, with the distaff of Omphale in his hand, is not more ridiculous, and out of character, than the virago, who affects the manners and pursuits appropriate to men. *Quæ fugit a sexu, vires amat.*

Nothing surely is better calculated to promote the general improvement of the species than that principle of love which leads the two sexes to desire and consult the happiness of each other. In the rudest state of society it has its influence. In such a state, indeed, woman is comparatively disregarded: her weakness and dependence render her completely subservient, and make her the degraded drudge of her rough and unpolished yoke-mate. In a state of ease, comfort, and affluence, woman becomes an object of greater consequence, but chiefly as an instrument of pleasure; she then studies the accomplishments which minister to luxury, and, perhaps, acquires considerable influence in society. But she is still in a state of moral degradation; and her beauty and accomplishments are valued by her lord as he values his plate, his equipage, and his furniture; that is, merely as the means of feeding his vanity and promoting his pleasure.

It is in the Christian system alone that woman assumes her true rank in society: for whilst it unfolds the virtues which confer the highest lustre on human nature, it shows that woman is equally susceptible of them with man, or rather, that her nature appears better adapted than that of man for the reception of them. Her feelings harmonize more readily with the mild and benevolent spirit of this religion: and human excellence being shown to consist in the cultivation of virtuous and pious affections, the female who is distinguished by these qualifications may justly aspire to the highest estimation in Christian society; and being, equally with man, the sharer of immortal hopes, she is entitled to the same consideration in the ordinary relations of life.

From what has been said, we think it will evidently appear, that our duty as moral agents may be inferred from the constitution of our nature, and the relations in which we are placed. We may say, with safety, that, to a certain extent, nature points out the line of duty: for we have seen that our appetites, desires, affections, &c. point most distinctly to certain ends, the attainment of which is considered necessary for happiness. But whilst our natural feelings impel us infallibly and irresistibly to desire certain gratifications, they do not point out, with precision, the means by which the end may be attained. These means are learnt by instruction, example, experience, and reason; and after the mind is thus informed, it perceives that the means of obtaining the enjoyments which we desire, though varied, are yet perfectly defined, and that we cannot neglect or abuse them without compromising our own happiness.

We may perceive, then, that the author of our nature has fenced in the path of virtue by numberless safeguards and securities, and which way soever we turn ourselves, we will find monitors of duty, and restraints imposed on vicious indulgence. Yet, with all these advantages, we need not be surprised at the struggles which are so frequently felt between inclination and duty. Such struggles are absolutely unavoidable, for the appetite is blind and indiscriminating; it may impel us to desire what we have no right to aspire to, and which cannot be ours without violating the rights of another. To feel hunger, and desire food, is perfectly natural, and, therefore, cannot be wrong: but it is contrary to justice to gratify this desire at the expense of another. To desire a beautiful woman may be equally natural, but it is wrong to seek the gratification of this desire, if she is already become the property of another. In short, our appetites, passions, and desires, require to be corrected by a consideration of the relations in which we stand to God and to society; and it is a considerable time before these are so distinctly perceived, as to operate surely and expeditiously in regulating the conduct.

Man's moral character results chiefly from his social connections, and these are not adventitious or fortuitously formed. Our analysis of some of the prominent feelings and circumstances of human nature had for its object to show that society, in its various forms and modifications, necessarily results from them; that man is made for social relations, and is gradually trained to discharge the duties required in them, by the moral and intellectual perceptions arising from the constitution of his nature.

Above all, the sense of religion, arising naturally at least, if not necessarily, out of the circumstances and constitution of man, tends to strengthen the power of moral obligation, and to afford an intelligible and universally applicable rule of duty. That it is absolutely necessary appears from this, that no nation has ever been able to do without it; and in every state of society religion has always been assumed as the sanction of morals. That it is so, must be admitted on every rational system of morals; for if there is a God who created all things, and established those laws which we feel ourselves bound to obey, we must evidently consider his will as the sovereign rule by which we ought to regulate our conduct. And if we set such considerations aside, we confess that we cannot perceive, by any powers of reason that we possess, any principle that will make a man forego evident advantages, and submit to serious privations, merely from a sense of duty: and we are more and more convinced that the sense of duty is an unintelligible phrase, or a principle without foundation, unless it be resolved into obedience to the divine law. A sense of interest may make a man avoid certain vices, such as gluttony, intemperance, and the like; but to discharge the relative duties, *a man must love his neighbour as himself;* and we know nothing that can produce this feeling but the conviction that God is the common father, governor, and judge of all.

The moral duties are alike binding on all, and no rank or condition can claim exemption from laws which, being founded on the nature of man, and the will of God, must necessarily be of universal obligation. The circumstances of individuals, however, are extremely various, and almost every man, from his particular situation and relations in society, will be called more frequently to the exercise of some moral duties than others. For these he acquires a fondness, and often displays a peculiar proneness to the performance of them. This is said to be the effect of *habit*, a quality which, whilst it gives additional security and facility to virtue, is not without some tendencies of an opposite character, against which we would do well to be on our guard.

The man who has been trained by habit to the exercise of a particular virtue, is very apt to view it with overweening fondness; and to be harsh and uncharitable in judging of others who do not show the same readiness and facility in the performance of it. The man who is distinguished by any virtue not exactly in the common line of practice, is always sure of an ample share of admiration. We think him something above the ordinary level of mortals, because he seems to do with ease and pleasure what would cost others much difficulty and pain to accomplish.

If the estimation of the world, in this respect, be not altogether correct, it is at least salutary in its influence, and we are more anxious to prevent undue elation in those who are thus distinguished, than to teach men to withhold the mead of praise from any thing that bears the appearance of virtue. In a rigid estimation of the subject, however, a man cannot reckon himself entitled to very high praise for the performance of duties to which he has been trained by a long course of discipline, or by powerful associations.

Dr. Reid has assigned some mysterious influence to *habit*, and has exalted it into an original principle of our nature. "It appears evident," says he, "that as, without instinct, the infant could not live to become a man, so, without habit, man would remain an infant through life, and would be as helpless, as unhandy, as speechless, and as much a child in understanding at threescore, as at three." He afterwards observes, "no man can show a reason why our doing a thing frequently should produce either facility or inclination to do it."

This is certainly putting *habit* out of its place, and making it usurp the province of a more important principle. How is it possible for this ingenious author to make out his position, that, without habit, a man would be as much a child in understanding at threescore as at three? Would not the memory retain the impressions which it had received, the knowledge which it had gained, and the facts which had passed in review before it, without any dependence on the power of habit? And, as we think habit not absolutely indispensable for the acquisition of knowledge, neither do we think that its influence over the human mind is absolutely unaccountable; at least, we think it may easily be referred to an ulterior principle.

In fact, we consider *habit* merely as one of the ordinary phenomena connected with memory and the association of ideas; and on this principle we think its power may easily be accounted for. Whatever has been once before the mind, will find a readier admission when presented a second time; for this plain reason, that it was at first a stranger, but is now recognized as an acquaintance. We might have had some difficulty at first, in understanding it, and it might have cost us a good deal of trouble to discover all its bearings and tendencies; but these difficulties being once removed, never recur; and the fact, or the feeling, or whatever it may be called, being treasured up in the memory, is added to the general stock of knowledge, and becomes, as it were, a new point from which we start in search of ulterior improvement.

But the recurrence of an idea or practice, however frequent, does not necessarily constitute habit. Though we wash our face every morning, or, every morning say our prayers, this is not habit. It is a regular custom, founded on expediency or reason. Neither do we apply the name of *habit* to any of those practices which result from the general constitution of our nature, and are observed by all mankind. We do not say that a man has a habit of taking his breakfast, or dinner, though he does so every day of his life, and has a most decided inclination to the practice. By a habit of eating, we would understand gluttony; as a habit of drinking always implies drunkenness. A man may have a habit of sleeping in his chair after dinner: we never talk of the regular repose of sleep as a habit. Perhaps there is as much of habit in the art of walking as in most things; yet, walking appears so natural, that we never consider it as a habit; but if a man limps without being lame, or slouches, or swaggers in his walk, we say he has acquired habits.

It is evident, then, that we apply the term *habits* to certain practices a little out of the ordinary way, when they obtain a very prominent influence; or to natural practices when carried to habitual excess.—Our moral habits may be explained in the same way. Particular circumstances give more importance in our imagination to one duty than to another. It has, for instance, been particularly enforced by the friend whom we admire; it has been recommended by some very interesting concomitants, or by some powerful considerations of public or private advantage: from these, and similar circumstances, it appears of paramount importance; and in our situation it may, in fact, be so; but we ought not to denounce, as deficient in moral sensibility, those who do not view it with the same rapturous feelings.

All prejudices are *habits* arising out of contracted education, illiberal society, or the example of those who have more influence than sense. All prejudices have a certain degree of moral obliquity attached to them: but, as the defect originates chiefly in the understanding, they may be called *bad intellectual habits*. We do not, in general, view such habits with much moral disapprobation. We are rather amused in tracing their origin; and regard them as the subject of ridicule, rather than of rigid censure. They have, however, a very extensive, and very pernicious influence on the happiness both of individuals and of society, as they obviously impair general benevolence, and obstruct general improvement.

To love the country in which we are born better than any other is not a prejudice: it is a natural, irresistible feeling: and the man who is a stranger to it, must be unacquainted with all the finer sensibilities of our nature. It is impossible to reflect on the scenes with which our recollections of youthful happiness are inseparably associated, without the most decided partiality: it is impossible to think of the place which contains the graves of our fathers, and of the companions of our early days, without feelings of the deepest interest: and a general predilection for our native country must arise in every well regulated mind, from a recollection of the social, civil, and religious ties which have so intimately connected our hearts with the country and community in which we have been brought up. Such feelings as these are not prejudices: for they arise out of natural and unavoidable associations; and there is a defect in the heart of every man who is a stranger to them. But if love to our country and connections leads us to despise other communities, or to hate and dislike those who differ from us in political institutions, in civil customs, or in national manners; in that case, we are under the dominion of the most narrow and hurtful prejudices, and will never be able to exhibit a single feature of general philanthropy, or of genuine christian spirit.

Prejudices in the case of certain contracted minds, and limited understandings, may be useful. They are a sort of substitute for steady principles; and we should be afraid that, were a weak man to renounce his prejudices, he might never find any principles so likely to secure consistency of conduct. On this ground, we are not displeased sometimes to see an obstinate man resisting enlargement of understanding, for he might lose what he would never be able to replace; and his mind might be set afloat without a single light to direct him. We have seen melancholy exemplifications of these observations in the case of many who have been trained up under the *prejudices* of religious education; we say prejudices, for their impressions never rose to the rank of rational principles.

When once they have been laughed out of that veneration which they had been accustomed to entertain for sacred subjects, they become the most disgusting profligates; and, by their nauseous licentiousness, rather do good than harm, to the cause which they mean to injure.

But when we talk of the good effects of any prejudice, we must be understood to speak only of those prejudices which lean to virtue's side. We have very little fault to find with that prejudice which makes a mother believe her own child the finest that ever was born; but there are few prejudices so harmless as this; they generally incline with preponderating bias to the wrong side; and often present insuperable obstacles to the dissemination of correct and enlightened principles. Prejudice is, in many cases, more dangerous than vice; a man can never have the effrontery to vindicate the latter; and however much he may be attached to it, he is generally ashamed to avow it. But the case is wholly different when a man is under the dominion of prejudice; he then glories in his delusion, and is ready to become a martyr to his error.

If what we have said on the subject of *habit* be correct, we ought to reckon all our vices *habits;* our virtues ought not to be accounted so, in our view of the foundation of morals, except when particular circumstances have given unusual prominence to some particular branch of a general duty.*

Few of the duties of life are indeed so obvious as to spring up spontaneously in the human mind; most of them are the result of experience, instruction, or example; and so far they may be accounted habits; as we often understand by that term all acquired qualities. But the general habits of right conduct, like the habits of speaking or walking, are so familiar to the generality of mankind, that we consider them as natural results; and, indeed, they may with propriety be reckoned so; for the leading truths of morality, though some of them may not be palpable at first view, become more obvious every time they are presented to the mind; it sees their bearings and connections more clearly, and perceives them to be enforced by a thousand analogous circumstances and events in the general economy of providence. They then become axioms, instead of corollaries; and that which was originally the result of painful study, and patient investigation, assumes the place of a first principle.

But vice is always contrary to right reason, and to the natural order of things; it is persisted in to the obvious detriment of our best interests; and it is only in consequence of a certain obliquity, introduced by habit into the physical and moral constitution of man, that it is enabled to hold its ground in the face of so many discouragements and dissuasives. Bad habits, by long indulgence, become almost irresistible; the man who has been accustomed to the stimulus of artificial excitement, becomes languid when it is withheld, and would as soon be deprived of meat and drink, as denied the gratification of his acquired appetites. The immediate consequence of excess is langour; a useful lesson to prevent repetition of the same offence against nature. But mankind have discovered artificial stimulants to overcome constitutional depression; and these will be most readily resorted to in time of need; where they are found to answer the purpose, reason has little chance in arguing against them; they have two most conclusive recommendations in their favour; they pre-

* We have here the authority of Aristotle against us. He says that virtue does not properly exist till it becomes the usual habit and disposition of the mind. "Thus the actinn which proceeds from an occasional fit of generosity is undoubtedly a generous action, but the man who performs it is not necessarily a generous person, because it may be the single action of the kind which he ever performed. The motive and disposition of heart, from which this action was performed, may have been quite just and proper: but as this happy mood seems to have been the effect rather of accidental humour than of any thing steady or permanent in the character, it can reflect no great honour on the performer. When we denominate a character generous or charitable, or virtuous in any respect, we mean to signify that the disposition expressed by each of those appellations is the usual and customary disposition of the person. But single actions of any kind, how proper and suitable soever, are of little consequence to show that this is the case. If a single action was sufficient to stamp the character of any virtue upon the person who performed it, the most worthless of mankind might lay claim to all the virtues; since there is no man who has not, upon some occasions, acted with prudence, justice, temperance and fortitude. But though single actinns, how laudable soever, reflect very little praise on the person who performs them, a single vicious action, performed by one whose conduct is usually very regular, greatly diminishes, and sometimes destroys altogether our opinion of his virtue. A single action of this kind sufficiently shows that his habits are not perfect, and that he is less to be depended upon, than, from the usual train of his behaviour, we might have been apt to imagine." Smith's *Review of Systems of Moral Philosophy*.

sent a remedy for present uneasiness, and they are much more palatable than lessons of self-denial, the only cure for the moral maladies of the human mind.

Hence we every day see attempts to reconcile luxury with health, and excess with enjoyment; and every such attempt has a tendency to perpetuate and strengthen the evil, and to render emancipation more hopeless. The son of Dion, who had been corrupted by Dionysius, chose to put an end to his own existence, rather than submit to the restraints which the wisdom of his father attempted to impose; and such facts are perfectly familiar to our observation, for we daily see men falling the voluntary victims of their vices, in spite of the most powerful motives and inducements to reformation of conduct.

It has often been observed, that bad habits are more steady and consistent in their operation than good ones; and it is not difficult to account for the fact. Our virtues carry us to the very verge of vice; that is to say, the slightest excess either in good or indifferent qualities, constitutes a moral offence; and how readily may even a good man be betrayed by the warmth of his feelings, by the influence of example, or of unexpected temptations! But bad habits never can make any approximation to the confines of virtue; the man who indulges them, has turned his back upon it; and every step that he advances carries him farther from the paths of wisdom.

In every judicious system of moral education, few things are more deserving of attention than the formation of habits. The great object to be aimed at in early culture, is the complete occupation of the mind by some employment which may lay the foundation of useful habits in after life; or, at least, may prevent the formation of such as are wrong. And where bad habits have been acquired, they are not to be conquered by the power of argument or of demonstration; they are to be overcome only through the influence of some counteracting practice, which must be made sufficiently interesting to engage the feelings, and abstract the attention from the hurtful habits which have engrossed it. To effect a reformation in such circumstances, is a work of extreme difficulty; but it ought not to be abandoned in despair. The most pernicious habits have often been acquired from the want of congenial employment; for if a man is either idle or forced to do what he dislikes, he has every chance to seek for pleasure from forbidden gratifications. We should think it advisable to give every young person who is not condemned to manual labour, as many securities as possible against the formation of evil habits; and ample resources are furnished in cultivating the pleasures of taste, or in the departments of the arts, or of elegant accomplishments, or of polite literature, or of scientific research, or of harmless amusement. And we believe it has often happened, that, from injudicious restraints, or from the mind being forced into an unnatural channel, the worst consequences have been produced; and the young have been led to seek from vice, that pleasure which might have been found more pure and ample in congenial occupations, or in innocent recreations. We are for diminishing none of the natural resources of human enjoyment; we would recommend them, not only as means of happiness, but as securities for virtue; and if vice is excluded, we shall not be much disposed to find fault with human employments. With this reservation, we would adopt the sentiment of Hesiod, even in the sense in which Socrates's accusers charged him with using it.

Εργον δ'ουδεν ονειδος, αεργειη δε τ' ονειδος.

On the Origin of Evil.

It has often been asked, how there should be so much sin and suffering, or so much vice and misery, in a world created and governed by a God of infinite wisdom and goodness. We do not know that a satisfactory answer has ever been given to this most difficult question; and in agitating the subject at present, we are far from entertaining the hope that we shall be able fully to resolve this *nodus* in the divine economy. The question, however, in one form or another, is indispensable in all discussions on morals: and, though much must necessarily remain unexplained, from the present imperfection of our faculties, we do not despair of removing the difficulty at least some steps farther back, or perhaps of carrying it to the point where acquiescence in the inscrutable will of heaven must put an end to our researches.

The Manichæan notion of two eternal, independent principles, the one good, and the other evil, was very early and extensively received in the East. According to this notion, there was a continual contest between these two principles, and their power was so equally balanced that neither of them could obtain a decided superiority: hence resulted that mixed state of vice and virtue, misery and happiness, so observable in the history of the world, and particularly in the life of man. They must have had very little philosophical observation who could rest satisfied with this clumsy hypothesis; for it is perfectly apparent, that all the physical evils at least (and these were the evils chiefly regarded in this scheme,) are not only reconcileable with the perfections of a wise and good Being, but are absolute indications of his wisdom and goodness in the present state of man.

A more modern hypothesis represents the existence of evil as necessarily arising out of the intractableness and imperfection of matter; from which qualities, some degree of imperfection and evil must be attached to every created thing.* This is intended as a vindication of the Creator: but even granting the premises, it does not answer the purpose; unless it could at the same time be shown, that God was under the necessity of acting, and of calling the world, as we now find it, into existence. For if the Deity had free-will and prescience, it would still remain to be shown, why he gave birth to creation, which must necessarily issue in evil and misery.

The only satisfactory answer to this is, that the evils we deplore are productive of good on the whole, and are essential to the moral discipline of man.

Pope, in attempting to vindicate the ways of God to man, has introduced a very gratuitous and inartificial

* Respondendum est, nihil quidem perfectionis et realitatis pure positivæ esse in creaturis earumque actibus bonis malisque, quod non Deo debeatur; sed imperfectionem actus in privatione consistere, et oriri ex originali limitatione creaturarum, quam jam tum in statu puræ possibilitatis (id est, in regione veritatum æternarum seu ideis divino intellectui obversantibus) habent ex essentia sua: nam quod limitatione careret, non creatura, sed Deus foret. Limitata autem dicitur creatura, quia limites seu terminos suæ magnitudinis, potentiæ, scientiæ, et cujuscunque perfectionis habet. Ita fundamentum mali est necessarium, sed ortus tamen contingens; id est, necessarium est ut mala sint possibilia, sed contingens est ut mala sint actualia: *non contingens*, autem, per harmoniam rerum, a potentia transit ad actum; ob convenientiam cum optima rerum serie cujus partem facit. *Leibnitz. Causa Dei Asserta*, &c.

hypothesis into his celebrated essay. He takes it for granted, that there is a regular gradation of existence rising through every possible variety, and that, therefore, there must be such a creature as man, and such a world as this.

> Of systems possible, if 'tis confest
> That wisdom infinite must make the best,
> Where all must fall, or not coherent be,
> And all that rises, rise in due degree;
> Then, in the scale of reasoning life, 'tis plain
> There must be somewhere such a rank as man.

This reasoning, if reasoning it can be called, is then confirmed by another hypothesis, in which it is assumed, or insinuated, that our present state of being has a reference to some other sphere, or system, as yet unknown. The reader must not suppose that this has any allusion to the commonly received doctrine of a future state. Nothing could be farther from the mind of the writer: he speaks of some system to whose convenience we are, at this moment, unconsciously subservient. This is evident from what he subjoins to his former reasoning.

> So man, who here seems principal alone,
> Perhaps acts second to some sphere unknown;
> Touches some wheel, or verges to some goal;
> 'Tis but a part we see, and not the whole.

It would be unfair to be very severe on this poetical system of the universe, in which splendid imagery and most beautiful versification make some atonement for the grievous deficiency of logical precision; and which is in fact not worse than a hundred other schemes which have been invented to account for the same thing. It is sufficient to say, that it consists wholly of gratuitous assumptions.

In stating the various theories that have been suggested to account for the origin and existence of evil, we may, without encroaching on the province of theology, be permitted to advert to the most ancient account of this subject; which is professedly not a theory, but a statement of historical facts. The account is, that God created man at first upright; but that he fell from his innocence and happiness by eating of the fruit of a certain tree, of which God had commanded him not to eat. There is no violation of probability or verisimilitude in this account. On the contrary, there are numerous memorials in the traditional histories of all nations, which bear a striking resemblance to this statement. The Grecian account approaches nearest to that of the sacred record. It celebrates the innocence and happiness of the golden age; and tells us that this desirable state of things was destroyed by the theft of Prometheus, who stole fire from heaven; and that the gods, to revenge his sacrilege, sent forth hosts of diseases and crimes to desolate the earth.

The coincidence between this account and that contained in Scripture, is too striking to be accidental. The offence and the punishment bear such a resemblance, that both accounts must evidently refer to the same event; and we would naturally assign the superiority, in point of authenticity, to the account which we know to be the most ancient. We do not, however, positively affirm, that the various accounts of the original innocence and fall of man, so widely disseminated throughout the world, have all been immediately derived from the Scripture history. We would rather suppose that the knowledge of these interesting facts was universally diffused; that it remained uncorrupted among the Jews, by being so early embodied in the record of their history and laws; whilst among other nations, being left to float down the uncertain channel of tradition, it assumed those various appearances which have so much obscured and disguised the truth.

The features of probability which distinguish the Scripture account, are, first, that God prescribed to man a test of obedience, in his state of innocence; for without such a test he could not have been a moral and accountable being: he could have had no choice between good and evil, and therefore could not have been a proper object either of punishment or reward. And, secondly, the test prescribed being of a positive and arbitrary kind, was perfectly adapted to the singular circumstances in which man was placed on his creation, in which, as far as we can perceive, he could only sin against an arbitrary statute.

But the difficulty lies not so much in ascertaining the manner in which evil was introduced, as in explaining the reason why it was permitted. Here we may observe, that evil could not have been absolutely prevented, without destroying the character of man, as a moral agent. The few intimations contained in Scripture, respecting the condition of the Angels, are in conformity with this idea. They also were made capable of sinning, in consequence of which some of them fell; whilst the rest, who withstood the trial, completed, in all probability, their probation by that resistance, and are now exempted from the possibility of falling; as the souls of the just shall be, when removed from this state of discipline into the blessedness of heaven. So far, then, our reason compels us to vindicate the Almighty for having made man

> "Sufficient to have stood, though free to fall."

Another ground of vindication is presented to us, when we consider that even the evils which are in the world, are productive of good on the whole. With regard to temporal or physical evils, this is undoubted. The human character is improved by suffering; and the evils which we most grievously deplore, if borne with fortitude, never fail to improve our natures, to increase our knowledge, and exalt our virtue. The havoc and devastation of war correct the licentiousness and effeminacy which result from peace; and difficulties and hardships give a vigour to the character, and an enlargement to the understanding, which never could have been acquired in the midst of ease and soft indulgence.

Even the mutual depredations of the lower animals which prey on each other, though we cannot suppose them productive of any thing like moral improvement, yet display a thousand resources provided by their Creator for their security and comfort; and in this way furnish to rational observers many striking proofs of the goodness and provident care of the Almighty. Besides, the very havoc which is made by mutual slaughter, increases the number of *genera* and *species*; and in consequence of the different tribes of animals preying on each other, provision is made for an infinitely greater variety and number than could have existed, had they all lived on one kind of food.

In short, the whole system of external nature seems completely adapted to man, as a creature born in ignorance, and continually liable to sin; and we might have inferred, though we had had no information on the subject, that the constitution of nature, or the system of the universe, was changed, when man forfeited his innocence, and became subject to sin; for as it exists at present it could have answered no purpose, in the primeval state of purity, but to impair human happiness. The Scripture account corresponds with this suggestion, or rather, perhaps, the suggestion itself has arisen out of the Scripture history; for we do not pretend to belong to that school of philosophy which would keep the mind completely uninfluenced by such considerations; and we have been taught from our infancy to believe, that the earth was cursed with sterility on account of man's transgression; and that the elements and system of nature were henceforth charged with hostility against the life and happiness of man.

At the same time, these evils serve both as punishments and correctives; their evident design being to obviate the evil tendency of our appetites, passions and affections; and whatever uneasiness they may cause, man, as his nature is now constituted, is undoubtedly happier than he would be without them.

But we do not pretend wholly to remove the difficulties connected with this question, when we endeavour to show that the outward arrangements of Providence are adapted with infinite wisdom to the present condition and circumstances of man. For the question is, How the condition of man came to be as we now find it; and why evil and suffering are permitted to find a place among the works of a good and merciful God? We will perhaps be fully as near our purpose to say at once, "Such is the will of Him who orders all things well and wisely." But men are not disposed to rest here; and they have anxiously laboured to separate the existence of evil from the ordinations of Heaven, affirming that though God *foresaw* the introduction of evil, yet he neither willed nor appointed it. This, however, will perhaps not appear to many quite satisfactory; for, as every thing depends on the Almighty, it may be said that his *prescience*, or knowledge of what is to happen, must have the same effect as an absolute decree.

There is one way of getting rid of this difficulty; but we fear it will not mend the matter much. It is affirmed, for instance, that *prescience* actually does not belong to God, and that any idea, implying either *Post* or *Præ*, must be totally inapplicable to a Being who fills eternity with his presence, with whom a thousand years are as one day, and one day as a thousand years. This is, no doubt, true; but if it is available for any thing, it is to silence, rather than to satisfy our reason, and to show us our utter incompetency to comprehend the things of God. It is of no use as an explanation, unless it could be shown that the actions of men are altogether independent on God, and that he could not prevent them from being what they are: but this would be vindicating his justice at the expense of his omnipotence, and exalting his mercy by denying his power.

We must not suppose that the Almighty has been directed in his determinations or decrees by any thing resembling the fate which the ancients represented as binding gods and men: we must conceive him to be perfectly free in his determinations and his actions; and though evil is permitted, we have reason to conclude that it could not be prevented, without the obstruction of a greater good. Hence the observation of Augustine, quoted with approbation by Thomas Aquinas and Leibnitz, *Deum permittere quædam mala fieri, ne multa bona impediantur.* The latter author observes, that every thing whose contrary implies a contradiction has a necessary existence; but every thing that might be otherwise than it is, though determined to be what it is, for sufficient and infallible reasons, is contingent. "Cela posé, l'on voit comment nous pouvons dire, avec plusieurs philosophes et theologiens célébrés, que la substance qui pense est portée à sa résolution par la représentation prévalente du bien ou du mal, et cela *certainement et infailliblement*, mais non pas nécessairement: c'est à dire, par des raisons qui l'inclinent sans la nécessiter. C'est pourquoi *les futurs contingens*, prévus et en eux-mêmes et par leur raisons, demeurent contingens; et Dieu a été porté infailliblement, par sa sagesse et par sa bonté, à créer le monde par sa puissance, et à lui donner la meilleure forme possible; mais il n'y étoit point porté nécessairement; et le tout s'est passé sans aucune diminution de sa liberté parfaite et souveraine. Et sans considération que nous venons de faire, je ne sais s'il seroit aisé to resoudre le nœud Gordien de la contingence et de la liberté." *Rémarques sur le Livre de l'Orig. du Mal.* And with regard to the existence of evil, under the administration of a Being powerful, wise and good, it is to be observed, that there is a wide difference between causing or appointing evil, and merely permitting it. This subject is illustrated by Jonathan Edwards by a striking analogy. "There is a vast difference," says he, "between the sun's being the *cause* of the lightsomeness and warmth of the atmosphere and brightness of gold and diamonds, by its presence and positive influence, and its being the *occasion* of darkness and frost in the night, by its motion, whereby it descends below the horizon." "If the sun were the proper *cause* of cold and darkness, it would be the *fountain* of these things, as it is the fountain of light and heat; and then something might be argued from the nature of cold and darkness to a likeness of nature in the sun; and it might be justly inferred, that the sun itself is dark and cold, and that his beams are black and frosty. But, from its being the cause no otherwise than by its departure, no such thing can be inferred, but the contrary: it may justly be argued, that the sun is a bright and hot body, if cold and darkness are found to be the consequence of its withdrawment; and the more constantly and necessarily these effects are connected with and confined to its absence, the more strongly does it argue the sun to be the fountain of light and heat. So, inasmuch as sin is not the fruit of any positive agency or influence of the Most High, but, on the contrary, arises from the withholding of his action and energy, and, under certain circumstances, necessarily follows on the want of his influence; this is no argument that he is sinful, or his operation evil, but, on the contrary, that he and his agency are altogether good and holy, and that he is the fountain of all holiness. It would be strange arguing, indeed, because men never commit sin, but only when God leaves them to themselves, and necessarily sin when he does so, and therefore their sin is not from themselves, but from God, and so that God must be a sinful Being: as strange as it would be to argue, because it is always dark when the sun is gone, and never dark when the sun is present, that therefore all darkness is from the sun, and that his disk and beams must needs be black."

But even the moral evils which are in the world, however destructive they may be to those with whom they originate, are productive of good, on the whole. In a state like the present, where man has to learn almost every thing by experience, instruction, or example, the aberrations of the wicked, and the obvious consequences of their sins, afford a useful lesson, and supply demonstrations of the danger of deviating from the plain path of rectitude, as pointed out by the ordinations of Heaven. Besides, we receive a clearer proof of the superintending providence of God in overruling the disorderly passions of men, and making them subservient to the purposes of his will, than if all went on regularly and smoothly, without a single jarring or discordant principle to disturb the harmony of the universe. Every man has his own centre towards which he would gravitate, or his own right line in which he would move, were he not drawn from it by some superior force which connects him with the general system of society. In short, the intention of the Almighty, both in the natural and moral world, seems to be, to produce regularity and order out of materials which are naturally inert or perverted; and so much of the *discordia semina rerum* is still to be seen, both in the elements of nature and in the constitution of human society, as to bespeak a present Deity to regulate and adjust them.

We have already shown, that the moral qualities of man are improved and exalted by the physical evils which he is called to encounter, and the same effect is produced by the moral evils to which he is exposed. The injuries and provocations of the wicked show the odious nature of the principles by which they are actuated, and produce in our minds a natural dislike of those qualities which offend us; whilst patience, and prudence, and meekness, and forgiveness, are called into exercise, and the mind which improves the lesson is purified, adorned and exalted.

But if any thing farther be wanting, as a compensation for the evils, moral and physical, which are in the world, or as a vindication of the benevolence of the Almighty, we conceive it is abundantly furnished by the promulgation of Christianity, which presents such a view of the divine benevolence and love to the human race, as we could not have formed a conception of, even in a state of paradisaical innocence and happiness. In short, this world, both in its physical and moral aspect, is exactly as the Almighty intended it should be. Why it is as it is, it would be as useless to inquire, as it would be to ask why God has made any thing as it is, or why he has bestowed on man, and the various tribes of animals, the powers and qualities which distinguish them. With regard to animals, we are satisfied with showing, that their faculties are adapted to their circumstances, and consider this as conclusive as to the goodness of God: and why should we not rest satisfied, and adopt the same conclusion, when we perceive that the present state of things is admirably adapted for the improvement of moral beings. Difficulties, indeed, frequently occur; but they are rendered useful for sharpening our faculties, and extending our knowledge, and it is impossible to mention an evil, for which the Almighty has not provided an adequate compensation.

There is no evil which men view with so much horror as death: exempt them but from this, and every other evil will appear tolerable;* yet, in so far as regards the general economy of nature, death cannot be accounted an evil. One generation passes away; but the loss is soon repaired; and the affairs of men go on with renovated vigour and increased knowledge, from the accumulated wisdom and experience of the ages which are past.

Of living things, there is not one that does not ardently desire to enjoy the continued blessing of existence; but it is not more inconsistent with the decrees of heaven than with general happiness and usefulness, that this desire should be indulged to any great extent. With regard to the human race, the near approach of death operates as a friendly monitor, in the case of every individual, to repress the extravagance of ambition, to teach sobriety of mind, and to stimulate to the acquisition of qualities which cannot be affected by the dissolution of the body.

Death, in its moral effects, is not only useful for individual improvement; but that general destruction which overwhelms successively every thing that lives, is, in fact, conducive to the general happiness and improvement of the human race.

Why should the present race of mortals monopolize the blessings of existence? After they have had their share in the business, the enjoyments, or the miseries of life, is it not reasonable that they should be removed from the stage, to give place to others who may taste the same pleasures,† and exhibit the same characteristic features of conduct, though diversified by various shades of improvement, and occasionally of deterioration? In so far as the wisdom and goodness of the Almighty are concerned, these attributes, we may safely affirm, are more conspicuously displayed in his giving life and enjoyment to successive millions of animated beings, than if the blessings of life were confined to the existing generation of men and animals.

As things are at present ordered by the wisdom of the Almighty, countless myriads of living creatures appear in succession to taste the blessings of existence, or to celebrate their Maker's praise, either by the voice of intelligence, or by the mute, yet expressive testimony of their actions. Nay, the dispensation of death, which we so generally deplore, furnishes scope for the enjoyment of some of the purest pleasures which man can experience here below. For the constant waste of the species is supplied by children born in our own image, in whose happiness we are deeply interested, whom we view as our representatives to other generations, and in whom our lives are so bound up, that death can scarcely appear even a natural evil, when we have transmitted, as it were, our existence and our comforts to others, whom we love as our own souls.

Thus, then, viewing that dispensation of the Almighty which has doomed all mankind to death, merely as a measure of the divine government, and unconnected

* The inordinate love of life is strongly pictured in the lines which represent the feelings of the effeminate Mæcenas:

Debilem facito manu,
Debilem pede, coxa,
Tuber adstrue gibberum,
Lubricos quate dentes;
Vita dum superest, bene est;
Hanc mihi, vel acuta
Si sedeam cruce, sustine.

† Lusisti satis, edisti satis, atque bibisti,
Tempus discedere.

with our particular feelings, it cannot but appear perfectly consistent with propriety and wisdom. It is useful for bringing a change of actors on the stage of human life, that old vices may be forgotten, that inveterate habits of wickedness may be destroyed, and that new improvements may be introduced in morals, politics, and religion; or that a fresh generation may admire and revere the fabric reared by the wisdom of their forefathers, or bequeathed to them by the bounty of heaven.

Could we view death as unconcerned spectators, we have little doubt that the conclusions which we have stated above, would appear convincing. But we cannot regard this grand consummation with feelings of indifference: it appears as a formidable evil and a terrible catastrophe to every one who values the blessings of life, or prizes the endearments of social intercourse; for all these must be surrendered; and to remain entirely unaffected under such prospects, would bespeak more insensibility than sound philosophy.

But this overpowering evil has a compensation in the hopes of immortality, which the light of nature taught the more virtuous among the heathen to cherish, and which Christianity has unfolded with the most commanding influence. The doctrine of the soul's immortality is second only to the notions which we entertain respecting the attributes of God, in its influence on the conduct of moral agents. It is made subsidiary to the laws in every state; and we have never known any nation under a regularly organized system of laws destitute of a belief of a future state. Warburton affirms, that the Jewish theocracy is an exception; and because the rewards of virtue, and the punishment of vice, under the Mosaic economy, are all of a visible and temporal kind, he infers that there must have been an immediate divine interference to encourage the righteous, and keep in awe the wicked. The argument may not hold in the full extent to which he carries it; but we have always thought it entitled to more attention than it generally receives, and to be deserving of other praise besides that of ingenuity and profound learning.

We conclude our speculations on the existence of evil, in the words of an American writer,* whose views on this subject coincide with our own. "It is difficult to handle the *necessity of evil* in such a manner as not to stumble such as are not above being alarmed at propositions which have an uncommon sound. But if philosophers will but reflect calmly on the matter, they will find, that, consistently with the unlimited power of the Supreme Cause, it may be said, that, in the best ordered system, *evils* must have a place." "If the Author and Governor of all things be infinitely perfect, then whatever is, is right. Of all possible systems, he hath chosen the *best;* and consequently there is *no absolute evil* in the universe. This being the case, all the seeming imperfections or evils in it, are such only in a partial view; and, with respect to the *whole* system, they are *goods*." "For if there be any evil in the system that is not good with respect to the *whole*, then is the *whole* not good, but evil, or at best very imperfect; and an author must be as his workmanship is; as is the effect, such is the cause. But the solution of this difficulty is at hand, that there is no evil in the universe. What! Are there no pains, no imperfections? Is there no misery, no vice, in the world? Or are not these evils? Evils indeed they are; that is, those of one sort are hurtful, and those of the other sort are equally hurtful and abominable; but they are not evil or mischievous with respect to the *whole*."

It forms a natural part in every regular discussion on moral science, to examine the foundation on which the important doctrine of the soul's immortality rests, with a view to ascertain its influence on human conduct.

With regard to the origin of this doctrine, it seems to stand much on the same footing as our belief in the being of a God; and the two together constitute the whole of natural theology. We suspect, however, that the doctrine of the soul's immortality is, in most cases, where it has not been expressly revealed, the result of traditional information, rather than the offspring of reason. It is true, indeed, that when once the doctrine is known, a thousand arguments may be adduced, both from the nature of God, and the moral constitution of man, to establish and confirm it; but whether the natural reason of man would have discovered it, is a question that cannot possibly be solved, unless we can find a nation cut off from all intercourse of knowledge, both with its contemporaries and predecessors.

Most of the ancient philosophers, with the exception of Epicurus and his followers, believed in the immortality of the soul. But many of them held the doctrine in a sense that rendered it inconsistent with a state of rewards and punishments in a future world; for they conceived the soul to be essentially immortal, as being an emanation from the divine nature, into which they supposed that it was again absorbed, when separated from its earth-born companion. Such an opinion as this necessarily destroyed any influence which the doctrine of immortality could have in repressing vice, or encouraging virtue, or alleviating misfortune; for if the soul is to have no distinct consciousness, and no separate existence after death, it could not be more materially affected even by annihilation; and on these principles we should be forced to subscribe to the opinion of Lucretius, who strenuously endeavours to establish the materiality and mortality of the soul.

> Nam si tantopere est animi mutata potestas,
> Omnis ut actarum exciderit retinentia rerum;
> Non, opinor, id ab letho jam longiter errat.

All the ancient philosophers who held the immortality of the soul, believed also in its pre-existence, or rather in its self-existence and eternity; having an idea that, if it had a beginning, it could not be necessarily immortal. Modern philosophers have been affected by this argument, and have, in consequence, been disposed to give up the idea of the natural immortality of the soul; ascribing its indestructibility to the decree of its Creator, and not to any quality inherent in itself. We certainly are not disposed to affirm, that the soul inherits immortality as an independent attribute. But we have no hesitation in affirming, that we can have no idea, from any thing we observe in the visible world, of the annihilation of any created substance. We see dissolution, separation, or division of parts, or alteration of form and figure; but by no process to which any material substance can be subjected, do we perceive any thing that approaches to annihilation. If a miracle was necessary to call matter into existence, we conceive that a miracle would be no less necessary to produce its annihilation and extinction.

* Turnbull.

On these principles, then, we do not think it quite evident that every thing which is created must be necessarily mortal. We ought rather to infer, that it has received an existence which nothing but a miraculous interference of divine power can destroy. But, whatever may be thought of the natural durability of material substances, it is evident that the soul is not composed of matter, and therefore cannot be affected by any of the accidents which seem to dissolve or to destroy it. The soul is conscious of feeling, thinking, judging, reasoning, qualities which it is not even possible to conceive to belong to matter. All the properties of matter may be reduced to extension, figure, colour, bulk, hardness, softness, and the like, which have no more resemblance to any of the known properties of mind, than a sunbeam has to the earth which it enlightens. Since, then, it is not possible to institute any comparison between the properties of mind and matter, it is evidently illogical and inconclusive, to argue that the soul must fall with our material bodies. The body is corrupted, changed, and disorganized, by the division or dissolution of its parts. This is the only idea that our senses present to us of death. But it is not even possible to conceive that the mind can be subjected to such a process; for it is not composed of parts: it is indivisible and indiscerptible, and cannot be affected by any of the accidents which alter or derange a material and divisible substance.

Another argument for the soul's immortality may be drawn from the faculties with which it is endowed. It is evidently possessed of powers capable of indefinite improvement: we can scarcely form an idea of any limits which can be set to its advancement. This improvement of the soul, however, is scarcely begun in the present world: a man has barely time to look about him, and contemplate the attainments to which he may aspire, when he is cut off in the very commencement of his career of improvement, and prevented from making those advances in virtue and knowledge, of which he feels his nature to be susceptible.

Now, we may reasonably ask, why such extensive capabilities should be given to the soul, if it is to be extinguished before they are evolved? It is a common observation, that God does nothing in vain; that there is nothing superfluous, unnecessary, or redundant, through all the works of nature; that every animal has organs and instincts adapted to its necessities and its uses; and is never furnished with faculties or propensities for which there is no adequate exercise or enjoyment. We may naturally conclude, then, that those faculties in man which enable him to contemplate the divine nature, and to resemble the divine perfections, are intended for a higher sphere of existence, where they will be fully unfolded and fully gratified; which is by no means the case in the present world.

Again: from every idea that we can form of God, we are forced to conclude, that he must be offended with vice, and pleased with virtue; and, of consequence, that the one will be punished, and the other rewarded. This, however, is evidently not done in the present world; for here vice often reigns triumphant, whilst virtue is calumniated and oppressed. We may, therefore, naturally conclude, that there must be a period of retribution, when all these irregularities shall be finally adjusted.

But, in truth, were God actually to punish and reward virtue in the present world, it would not remove one of our doubts and difficulties as to the equity of the divine administration, unless we were possessed of the omniscience of the Sovereign Judge, and knew precisely all the motives by which the actors have been influenced; for in these alone consists the merit and the demerit of their conduct. As such knowledge as this is wisely denied us in the present world, the season of final retribution is properly deferred till the time when the secrets of every heart shall be made known, and the whole universe made to recognise the justice and wisdom of the divine administration.

It is indeed said, that virtue is its own reward, and vice its own punishment, even in the present world; and certainly it cannot be denied, that the man who violates the eternal laws of providence will find himself punished in the very transgression. But a cautious sinner may avoid all these consequences; he may be filled with envy, malignity, dishonesty, and every evil affection; his character may be stained with every shade and degree of moral turpitude in the sight of God, whilst it appears spotless and unsullied in the eyes of men. There is no temporal punishment provided for such guilt as this; even conscience does not necessarily prove an avenger; on the contrary, the wretch may find a kind of fiend-like enjoyment in the gratification of his unhallowed affections. We grant, indeed, that the virtuous may experience much happiness in the approbation of their conscience, even amidst the troubles and calamities of life; but this is only in consequence of a conviction that they are acting according to the eternal rules of rectitude which God has established, and that consequently their conduct must be pleasing to him. The wicked, on the other hand, often experience the greatest torture in the compunction and remorse of their consciences; but this arises solely from the fear of future punishment, which their guilty consciences tell them they have deserved.

Such are some of the arguments which the light of nature furnishes in favour of the soul's immortality; a doctrine which has had a most extensive reception, and a no less extensive influence in every state of human society. The vulgar, who were not misled by philosophical speculations, had distinct views of a state of reward and punishment; and though their creed was, in many respects, very erroneous, and very absurd, we firmly believe that it had more efficacy than all the laws that ever were invented by man, in directing to that line of conduct which was conceived to be agreeable to the will of the gods.

The question of Liberty and Necessity.

The question of *liberty* and *necessity* has always been conceived to be intimately connected with morals; and has had a place in almost all systems of moral science. Yet none has been involved in such perplexity; and on none do the opinions of writers appear so diametrically opposite to each other. We consider this as a sure proof that they do not understand each other's reasoning, or that they affix totally different ideas to the terms in which their propositions are announced; and whilst they are exhausting their ingenuity in demolishing the arguments of their adversaries, they are very often only combating the phantoms which their own imagination has raised. The advocates for *liberty*, on the one hand, charge the opposite doctrine with many tremendous consequences. They represent it as subversive of all moral agency, as breaking down the fences of virtue, and opening the door to immorality and irreligion. And it must be confessed, that Hobbes and others have held the doctrine in such a form as fully to authorize these conclusions. But, on the other hand, Leibnitz and Edwards state the doctrine of necessity in such a way, as to vindicate it from all such charges; and the latter author undertakes to demonstrate, that the opposite scheme infallibly brings along with it all the evil consequences which its advocates have attempted to connect with the doctrine of necessity.

It is evident from this, that there must be some grievous misunderstanding on the one side or the other; for without this, it would be impossible to conceive that men of learning and ingenuity, as the disputants in this controversy generally are, should arrive at such opposite conclusions on the same subject. Whether we shall be able to untie this Gordian knot to the satisfaction of our readers, we think is very doubtful. We shall endeavour, however, to give a fair view of the question, and shall state without reserve our own opinion.

The advocates for liberty are hard pressed by the argument that the will is influenced by the last determination of the understanding, or by previous habits, or by that which appears at the time most desirable. If they admit this, the question is decided; for that liberty which they reckon essential to moral action is destroyed. This is confessed by Archbishop King,* who brings the matter to a very distressing dilemma; for he says, that if the will is influenced by reason, it is not free; and, if it is not thus influenced, it acts irrationally. One would not think it easy to escape from the horns of this dilemma; but this author attempts it by a method almost peculiar to himself; for, with the exception of his very able commentator, we scarcely know any who has adopted it. His scheme is, that "things are not chosen because they are good, but become good because they are chosen."

We would here notice the strange idea that this author, and indeed almost all the advocates for liberty, entertain respecting the nature of human freedom. According to their notion, a perfectly wise and good man, who cannot possibly *will* what is foolish or wicked, is subject to a necessity destructive of virtue and moral responsibility. On the same principle, it might be said that the Supreme Cause cannot be free, because he cannot but do that which is wisest and best. This, as Dr. Clarke observes, is a necessity, not of nature or of fate, but of fitness and wisdom; a necessity consistent with the greatest freedom and most perfect choice; for the only foundation of this necessity is such an unalterable rectitude of will, and perfection of wisdom, as makes it impossible for a wise being to act foolishly. "Though God is a most perfect and free agent, says the same author, yet he cannot but do always what is best and wisest on the whole. The reason is evident; because perfect wisdom and goodness are as steady and certain principles of action, as *necessity* itself; and an infinitely wise and good Being, endued with the most perfect liberty, can no more choose to act in contradiction to wisdom and goodness, than a necessary agent can act contrary to the necessity by which it is acted; it being as great an absurdity and impossibility in choice, for infinite wisdom to choose to act unwisely, or infinite goodness to choose what is not good, as it would be in nature for absolute necessity to fail of producing its necessary effect."

We may apply this subject to human agents in the words of Mr. Locke. "'Tis not a fault, but a perfection of our nature, to desire, will, and act, according to the last result of a fair examination. This is so far from being a restraint or diminution of freedom, that it is the very improvement and benefit of it: it is not an abridgement, it is the end and use of our liberty; and the farther we are removed from such a determination, the nearer we are to misery and slavery. A perfect indifference in the mind, not determinable by its last judgment of the good or evil that is thought to attend its choice, would be so far from being an advantage and excellency of any intellectual nature, that it would be as great an imperfection, as the want of indifferency to act or not to act, till determined by the will, would be an imperfection on the other side. It is as much a perfection, that desire or the power of preferring should be determined by good, as that the power of acting should be determined by the will; and the certainer such determination is, the greater the perfection. Nay, were we determined by any thing but the last result of our own minds, judging of the good or evil of any action, we were not free. The very end of our freedom being, that we might attain the good we choose; and, therefore, every man is brought under a necessity, by his constitution as an intelligent being, to be determined in willing, by his own thought and judgment, what is best for him to do; else he would be under the determination of some other than himself, which is want of liberty. And to deny that a man's will in every determination follows his own judgment, is to say that a man wills and acts for an end he would not have, at the same time that he wills and acts for it. For if he prefers it in his present thoughts before any other, it is plain he then thinks better of it, and would have it before any other; unless he can have, and not have it, will, and not will it, at the same time; a contradiction too manifest to be admitted. If to break loose from the conduct of reason, and to want that restraint of examination and judgment, that keeps us from doing or choosing the worse, be liberty, madmen and fools are the only free men. Yet I think nobody would choose to be mad, for the sake of such liberty, but he that is mad already."

King gives up all idea of vindicating the freedom of the human will on any other principle than that which he has adopted, viz. that things chosen derive their value from the choice of the mind; and we think it may be fairly concluded, that the cause is lost if it has no better support. He complains that the friends of the opposite doctrine deal in subtleties, and in arguments remote from common feeling and common apprehension. But the charge may with justice be retorted on himself, and it may be affirmed, that none has ever advanced such a paradoxical argument on the subject, nor maintained it by such subtle and paradoxical reasoning. It is indeed gratifying to think of the mind's omnipotence, and of its superiority over the circumstances of time, place, and accident; and there can be no doubt, that, with proper regulation, it may be the fabricator of its own happiness. But this is not to be effected by a mere independent fiat of the will, and by the creation of means to secure happiness; but by a judicious application and proper use of those circumstances which are presented in the arrangements of Providence. Before the mind can have that independence on circumstances which this author assigns to it, it would require to be not only omnipotent, but omniscient. It must either be omnipotent, to model events

* Origin of Evil.

by a simple volition, as the Almighty did, when he called all things into existence; or it must be omniscient, that its volitions may not interfere with the established order of nature: but the author claims neither of these attributes for it, when he asserts its independence on nature, judgment, association, and reasoning. All that he claims for it is, that it should be able to discern the things which are possible from those which are impossible, and thus provided, it has its happiness completely in its own power. "That person must be happy," says he, "who can always please himself; but this agent can evidently do so. For since things are supposed to please him, not by any necessity of nature, but by mere election, and there is nothing which can compel him to choose this rather than another; it is plain that the agent endowed with this power may always choose such things as it can enjoy, and refuse, that is, not desire or not choose those things which are impossible to be had. And from hence it appears of how great importance it is, whether that whereby things become agreeable to the appetite, be established by nature, or effected by the agent himself. For if good and evil proceed from nature, and be inherent in objects, so as to render them agreeable or disagreeable antecedent to the election, the happiness of this agent will always depend upon them; and unless the whole series of things be so ordered, that nothing can happen contrary to his appetites, he must fall short of happiness."

Now, though we certainly should be sorry to countenance the doctrine, that a man's happiness is entirely at the mercy of external circumstances; (for there are many *rational* considerations which tend to diminish the influence which adverse circumstances would otherwise exert over our happiness;) yet we affirm, with perfect confidence, that there are pains, trials, and disappointments, which must produce unhappiness, unless they are counteracted by reason, hope, or religion. According to the doctrine which we are combating, a man when placed on the rack ought not to be unhappy; for the mind is altogether independent on such circumstances. But certainly there is no man whose feelings are not paralysed by disease, but must feel pain in such circumstances; and if pain be not an evil, then the ingenious author should have given a different form to his very important, though in many respects very eccentric, Essay on the Origin and Tendency of Evil; and should have endeavoured to show that no such thing as evil exists in the universe.

This holds undoubtedly true with regard to physical evil; for if there be nothing in external circumstances which has a direct tendency to affect our happiness, then it is idle to talk, as the author has done at so great length in the first part of his book, of the physical evils of hunger, disease, death, &c. And Leibnitz has shewn no less clearly, that if the mind choose without a motive, there can be no moral evil; for moral evil consists in a wrong choice, and if there be nothing to direct the choice, how can it be wrong? "Dans le fond, bien loin que ce soit montrer la source du mal moral, c'est vouloir qu'il n'y en ait aucune. Car si la volonté se determine sans qu'il y ait rien, ni dans la personne que choisit. ni dans l'objet qui est choisi, qui puisse porter au choix, il n'y aura aucune cause, ni raison de cette election: et comme le mal moral consiste dans le mauvais choix, c'est avouer, que le mal moral n'a point de source du tout. Ainsi dans les regles de la bonne metaphysique, il fraudroit qu'il n'y eut point de mal moral dans la nature; et aussi par la meme raison, il n'y auroit point de *bien moral* non plus, et toute la moralité seroit detruite." *Remarques sur la Livre de l'Origine du Mal.*

Hume has observed, and there is undoubtedly truth in the observation, that we can trace a general course of human conduct almost with as much certainty as we can trace a general course of nature; that is, we may pronounce that men will act in a certain way in given circumstances with as much confidence, as that trees will grow in a given situation: and he justly considers this determination which the conduct receives from circumstances as subversive of that liberty for which many contend. Yet, unless we can remove this influence of motives, that *indifference* which is reckoned essential to liberty is completely destroyed. And how is it possible to remove this influence? It is directly contrary to the whole scheme of our philosophy to suppose it possible; for we have assumed it as an unquestionable principle, that the general course of nature influences both our moral and intellectual associations: that with regard to intellectual attainments, the mind does little more than methodize the facts, and treasure up the relations presented in the course of nature; and the whole of this article has been conducted on the supposition that our volitions are influenced with infallible certainty, by the circumstances of our nature, and the visible arrangements of providence. The beautiful order which we observe among the works of God is intended to facilitate the acquisition of knowledge, and render the path to the temple of science attractive and delightful; and it is equally intended to influence our volitions and our moral perceptions; for it would be a most extraordinary inconsistency, to affirm that God has formed arrangements for human happiness, and yet that men act at random, without any regard to the manifest will of heaven.

The advocates of liberty contend that the scheme of necessity renders means, exhortations, promises, and threatenings, altogether unavailing. Without stopping to obviate this, at present, we would merely observe, that their own plan must produce this effect in a tenfold degree, for it lies at the foundation of their scheme, that motives do not influence; for if they did, there would be an end of liberty; and if motives do not influence, what is the use of exhortations, promises, or threatenings.

But will any man, whose ideas are unsophisticated by a philosophical or theological system, pretend to say that the mind is not influenced by instinct, education, association, habit, passion, prejudice, &c. &c.? And if if it be thus influenced, there is an end of indifference of choice, and with it of liberty. Law, in his commentary on King's Essay, supports the principle of *indifference* by the following reasoning. "Let a thing appear never so pleasant and agreeable, never so reasonable, fit, and eligible to us, yet there is still a *natural* possibility for us to will the contrary, and consequently the *bare power of willing* is in itself indifferent to either side." There is a fallacy here. In perception, the mind is almost wholly passive, and simply receives the impressions made upon it through the medium of the senses; in volition it is wholly active. Volition does not, like perception, impart any feeling to the mind; it is merely the organ or instrument, by means of which the mind manifests its determinations; and the will never can be indifferent when it is in action; when it is not in action, it is in nonentity. And with regard to what this author says, that there is a *natural possibility* for the mind to form a choice, in opposition to every perceived advantage, and every preponderating circumstance, the fact is admitted by every enlightened *necessitarian*, and he only wishes this author, and all who favour his sentiments, to keep in mind the distinction between *physical* and *moral* impossibility. These are generally, perhaps industriously, confounded by the advocates for liberty, with a view to bring odium on the opposite doctrine; and they represent the scheme of necessity as resembling a tyrant, who should bind a man to the ground with fetters, and then punish him because he does not, in these circumstances, obey the command to rise and walk.

There cannot be a grosser misrepresentation of the doctrine. In the supposed case the mind is free, but the body is subject to physical restraints, which prevent volition from issuing in action. But in all moral delinquencies, the mind is indisposed or enslaved; and the inability to act proceeds only from its own want of inclination. No restraint whatever is laid on the mind; it goes wrong, not in consequence of any perceived constraint, but merely by yielding to the bias of its own inclinations. However strong any temptation may be, no man can say that it is *absolutely* irresistable; were it so, it would amount to *physical impossibility*, and would exempt from all blame, and from all moral impossibility. But the man who yields to temptation is only subject to a *moral inability*, induced by bad habits, which he has no inclination to resist. In short, he *wills* to go wrong, and with his own full and perfect consent runs headlong into vice or folly. Physical restraint is always palpable; moral restraint cannot be so: for the evil rests in the will itself, or, to speak more properly, in the mind which actuates the will: and it is not sensible either of restriction or constraint whilst it is following the decided bent of its inclinations.

Would it not, then, be in the highest degree absurd, for any man to complain that his liberty is impaired, when he is both *willing* and *acting* as he pleases. And this species of liberty, and it is the only one of which we have any conception, is left entire by the advocates for necessity. But the liberty of indifference, so much contended for, is incomprehensible. If it consists in acting without motives, there can be no more merit or demerit in the actions than if they proceeded from blind fate or accident; or if it consist in the power of acting contrary to motives, it cannot surely be thought a very enviable prerogative to have the privilege of acting in opposition to reason.

That we are influenced by motives is certain: the person who despises them is not entitled to the appellation of a rational being: and that God has intended that we should be influenced in a particular way, is no less certain; for our instincts, appetites, and passions have distinct and definite objects, to which they are adapted; and the whole course of nature and providence co-operates with them in directing our conduct to particular ends. So far, then, we may say, without hesitation, that the liberty of indifference is destroyed by the decree of heaven; and that God himself, by the arrangements of his providence, has controlled the volitions and the conduct of men.

Shall we then ascribe to God the sins of men, and the various aberrations of human conduct? This consequence would be unavoidable, were men swayed by a *physical* necessity, and did their reason tell them that it is *absolutely* impossible to resist the suggestions to evil. But the case is directly the reverse. Instead of being constrained to do wrong, by a *physical* necessity, it is quite apparent that God has done every thing, as far as is consistent with the moral responsibility of man, to cast the balance on the other side, and to constrain human beings to walk in the paths of virtue. The miserable consequences of transgression, conscience, reason, sympathy, together with every original or accessary feeling of our nature, concur in lending their influence to strengthen the obligations of moral duty. They, in fact, do all *but absolutely compel us*, to make us virtuous and happy. And so far from feeling ourselves, in any instance, constrained to do evil, the compunctions of conscience are sharpened by the conviction, that we have acted in opposition to the most obvious inducements to virtue. Whatever necessity, then, there is arising out of the appointments of heaven, it is all on the side of virtue; and the self-condemnation of the offender arises from the consciousness of having resisted it. Every thing presented in the economy of the Divine government is either positively good, or capable of being turned to good. Riches, power, and honours are designed by heaven to be the rewards of industry, bravery, or virtue: and no man can say that God has misled him, if he aspires to the reward by means which are not consecrated by the appointment of heaven; and he has no reason to complain, if he finds misery and disgrace, instead of the pleasures which he anticipates. He cannot say that he mistook the means; it is evident that he understood them perfectly, by exhibiting the semblance of those virtues which God delights to honour: but he expects to reach the end by a shorter way than that which is prescribed by the course of Providence; and he reaps misery as the reward of his furtive attempts to elude the decrees of heaven.

No man can say that he is constrained to do evil by the circumstances in which he is placed: for, as it has been said, *every thing has two handles*, and, according as it is employed, may be the means of good, or the instrument of evil. A man's virtue and happiness are ruined, we shall suppose, in certain circumstances; and it is common for him to say, and for the world to believe him, that had he not been placed in such circumstances, he would have been happy and good. But it is not his circumstances, nor consequently the appointments of heaven, which he ought to blame; for he may see thousands, both virtuous and happy, in the same circumstances in which he ceased to be either.

Let no man then blame necessity for his sins. He is almost constrained to be virtuous: if the constraint were complete, he would not be a moral agent, nor the same being that he now is.

We readily admit that there are many things in the economy of the Divine administration which it is quite impossible for finite understandings to comprehend; and to no subject is this observation more applicable than to the one we are now considering. For we admit most readily, that could we even demonstrate the view of the subject we have adopted, and which we think might be brought as near to demonstration as any point in morals or religion can be, yet even then difficulties would not be wholly removed: nor will we presume to say that we can satisfactorily explain all the ways of God on our plan. We believe the same admission will be made by every candid disputant on the other side; and the question comes to be, which scheme presents fewest difficulties, and solves the greatest number of doubts. The doctrine of necessity is by no means the most popular, but we are fully convinced that it is by far the most philosophical, and that its antagonist doctrine cannot stand before it in point of argument. The objections to *necessity* are all of a popular cast; and in removing them it will generally appear that we demolish the opposite doctrine.

If the advocates for liberty say that it consists in *a man's willing what he pleases*, and this is their common language, no necessitarian can have any dispute with them on this point: the proposition is intuitively true, or rather it is a truism—for a man never can will any thing but what he pleases, unless it were possible for him to will and not to will the same thing at the same time. Whatever a man wills must, at the moment, please him, or he must consider it most eligible at the time—in fact, the expression is tantamount to saying that *a man chooses what he chooses*. Whatever volition the mind forms must be consistent with its choice, for choice and volition *are* the same thing: *they imply the determination or election which the mind has formed*, and, therefore, whenever volition is exerted, liberty is at an end. The mind has already received its impulse—it is already in action, and the quiescence, and indifference, supposed to be essential to liberty, have completely vanished.

The proper question then is, What is it that induces the mind to will? And we think it ought to be admitted as an axiom, that if it is swayed by any thing external to it, and independent of it, or even if it is swayed by any thing essential to its own nature, in neither of these views can it be said to be free, in the sense in which freedom is usually understood, as applied to the human mind. Indeed, it seems to be a most unreasonable freedom that is contended for; it must arise without a cause from the *self-determining* power of the mind. Now, a self-determining power cannot be influenced by any thing, otherwise it is not self-determined; and if it is not influenced by any thing, then it is a power existing without a cause, of which we can have no conception, except in the case of the Supreme Being.

Considering the subject speculatively, one might perhaps be at a loss to determine which of the two schemes is most likely to be abused; for we think it should equally exempt a man from responsibility, to suppose that he has *insufficient* motives to influence his conduct, or that he is bound by *absolute irresistible necessity.* If the author of our nature has not given us sufficient inducements to rectitude of conduct, or, in other words, if he has not presented motives sufficiently powerful to influence our will, we cannot well see how we should be answerable for the want of proper volitions; if, on the other hand, our wills are *absolutely* controlled, there could be no such things as virtue or vice in the world.

As we have ventured to take a side in this very difficult question, we shall rest satisfied with vindicating our peculiar views from the objections which have frequently been urged against them. And, first, it is said that necessity is altogether inconsistent either with praise or with blame. *Physical necessity*, or coercion, is undoubtedly inconsistent with praise or blame. But this is not the case with *moral necessity*, otherwise we could not ascribe praise and glory to the Most High, who undoubtedly acts under a moral necessity, for it is *impossible* for him to do evil; not that he wants the power to do so, but because it is impossible for a being infinitely wise and good, ever to have an *inclination* to do evil; and, according as a man advances in wisdom and goodness, he comes so much nearer to a moral necessity of doing what is right, which, instead of being a defect, constitutes the perfection of his nature. Habits and prepossessions in favour of virtue, which undoubtedly destroy the equilibrium of indifference, and consequently impair or destroy the freedom of the will, so far from lessening our ideas of the worth of the agent, increase them in the highest degree; and where we see a fixed and determined bias to virtuous actions, there we place our highest veneration and esteem. On the other hand, a man who is habitually vicious, and so strongly biassed and inclined to evil, as to be incapable of virtuous exertion, is always viewed with additional abhorrence, instead of being considered as excused by the moral inability under which he labours. Moral inability, then, is never considered as any excuse for wickedness, and the nearer it approaches to moral impossibility, the character is considered as so much the more infamous.

The argument may be carried farther still. "If it be supposed that good or evil dispositions are implanted in the hearts of men by nature itself, yet it is not commonly supposed that men are worthy of no praise or dispraise for such dispositions: although what is natural is undoubtedly necessary, nature being prior to all acts of the will whatever. Thus, for instance, if a man appears to be of a very haughty or malicious disposition, and is supposed to be so by his natural temper, it is no vulgar notion, no dictate of the common sense and apprehension of men, that such dispositions are no vices or moral evils, or that such persons are not worthy of disesteem, or odium, or dishonour, or that the proud or malicious acts which flow from such natural dispositions, are worthy of no resentment. Yea, such vile natural dispositions, and the strength of them, will commonly be mentioned rather as an aggravation of the wicked acts that come from such a fountain, than an extenuation of them. Its being natural for men to act thus, is often observed by men in the height of their indignation; they will say, 'It is his very nature; he is of a vile natural temper; it is as natural to him to act so, as it is to breathe; he cannot help serving the devil.' But it is not thus with regard to hurtful, mischievous things, that any are the subjects or occasions of by natural necessity, against their inclinations. In such a case, the necessity, by the common voice of mankind, will be spoken of as a full excuse. Thus, it is very plain, that common sense makes a vast difference between these two kinds of necessity, as to the judgment it makes of their influence on the moral quality and desert of men's actions."*

In the *second* place, it is said that the scheme of necessity is inconsistent with the use of means, and that if virtue or vice come to pass by necessity, it must be useless to employ any means to obtain the one or avoid the other. This is a very groundless objection, and may, with great advantage, be retorted on the opposite scheme. The whole scheme of necessity proceeds on the idea, that there is a necessary connection between means and ends, antecedents and consequents. "Itaque tantum abest, ut prædeterminatio seu prædispositio ex causis necessitatem inducat contrariam contingenti vel libertati aut moralitati; ut potius in hoc ipso distinguatur *fatum Mahometanum* a Christiano, absur-

* Edwards on Free Will.

dum a rationali; quod Turcæ causas non curant; Christiani vero et quicunque sapiunt, effectum ex causa deducunt. Turcæ silicet, ut fama est, (quanquam non omnes sic desipere putem,) frustra pestem et alia mala evitari arbitrantur; idque eo praetextu quod futura vel decreta eventura sint, *quicquid agas aut non agas*, quod falsum est: cum ratio dictet eum qui certo peste moriturus est, etiam certissime causas pestis non esse evitaturum. Nempe, ut recte Germanico proverbio dicitur, mors vult habere causam." Leibnitz.

It is, then, evidently inconsistent to object to the necessitarian that his scheme renders means unavailing, when he holds that there is a necessary connection between means and ends, motives and action: that when certain means are employed, certain ends will follow; and that certain motives will as certainly lead to particular actions. With much greater justice may it be said, that the opposite scheme supersedes the use of means; for if there be no fixed and established connection between means and ends, and the advocates for liberty are bound to maintain that there is not, for on any other supposition, their scheme falls to the ground; then, it would follow, that it matters not what means are employed, or whether any are employed at all. There could be no such thing as acting with wisdom or prudence, if we did not see an established connection between certain actions or events in the shape of means, and others which depend upon them as their consequents.

We apprehend it is time to close this discussion. We readily admit that the scheme of necessity which we have adopted has often been abused and perverted, by bad men, to the worst of purposes: the Turkish view of predestination is neither more nor less than a gross abuse of the doctrine of necessity: and it is certain that ignorant religionists have perverted it in the same way in many Christian countries. We have endeavoured to vindicate the doctrine from such misconceptions: and though we readily admit that there are many difficulties on the subject of moral agency, which we cannot pretend to explain, yet we think there are fewer on the scheme of necessity, when rightly understood, than on the generally received views of liberty.

Our readers will thank us for presenting them with the opinion of a very acute writer* on this subject, who conveys much weighty matter in small compass, and states some important considerations, which ought to be taken into view by disputants on both sides of the question. "So far as these necessarians maintain the certain influence of moral motives, as the natural and sufficient means whereby human actions, and even human thoughts, are brought into that continued chain of causes and effects, which, taking its beginning in the operations of the infinite mind, cannot but be fully understood by him; so far they do service to the cause of truth; placing the great and glorious doctrines of foreknowledge and providence—absolute foreknowledge, universal providence, upon a firm and philosophical foundation." Thus far we profess ourselves the advocates for necessity, and we assent fully to the following observations, which are both just and profound. "But when they go beyond this, when they would represent this influence of moral motives as arising from a physical necessity, the very same which excites and governs the motions of the inanimate creation—here they confound nature's distinctions, and contradict the very principles they would seem to have established. The source of their mistake is this, that they imagine a similitude between things which admit of no comparison—between the influence of a moral motive upon the mind, and that of mechanical force upon matter. A moral motive and a mechanical force are both indeed causes, and equally certain causes each of its proper effect; but they are causes in very different senses of the word, and derive their energy from the most opposite principles. Force is only another name for an *efficient* cause; it is that which impresses motion upon body, the passive recipient of a foreign impulse. A moral motive is what is more significantly called the *final* cause, and can have no influence but with a being that proposes to itself an end, chooses means, and thus puts itself in action. It is true, that while this is my end, and while I conceive these to be the means, a definite act will as certainly follow that definite choice and judgment of my mind, provided I be free from all external restraint and impediment, as a determinate motion will be excited in a body by a force applied in a given direction. There is in both cases an equal certainty of the effect; but the principle of the certainty in the one case and in the other is entirely different, which difference necessarily arises from the different nature of final and efficient causes. Every cause, except it be the will of the Supreme Deity, acting to the first production of substances—every cause, I say, except this acting in this singular instance, produces its effect by acting *upon* something; and whatever be the cause that acts, the principle of certainty lies in a capacity in the thing on which it acts, of being affected by that action. Now, the capacity which force, or an efficient cause, requires in the object of its action, is absolute inertness. But intelligence and liberty constitute the capacity of being influenced by a final cause—by a moral motive; and to this very liberty does this sort of cause owe its whole efficacy, the whole certainty of its operation; which certainty never can disprove the existence of that liberty upon which it is itself founded, and of which it affords the highest evidence."

The following observations also, by the same author, on the general aspect of the question, are both moderate and judicious, and highly deserving of the attention of every one who engages in this controversy. "The liberty of man and the foreknowledge of God are equally certain, although the proof of each rests on different principles. Our feelings prove to every one of us that we are free: reason and revelation teach us that the Deity knows and governs all things—that even 'the thoughts of man he understandeth long before,' long before the thoughts arise—long before the man himself is born who is to think them. Now, when two distinct propositions are separately proved, each by its proper evidence, it is not a reason for denying either, that the human mind, upon the first hasty view, imagines a repugnance, and may perhaps find a difficulty in connecting them, even after the distinct proof of each is clearly perceived and understood. There is a wide difference between a paradox and a contradiction. Both, indeed, consist of two distinct propositions, and so far only are they alike: for of the two parts of contradiction, the one or the other must necessarily be false; of a paradox, both are often true, and yet, when proved

* Bishop Horseley.

to be true, may continue paradoxical. This is the necessary consequence of our partial view of things. An intellect to which nothing should be paradoxical would be infinite. It may naturally be supposed that paradoxes must abound the most in metaphysics and divinity, *for who can find out God unto perfection?* Yet they occur in other subjects; and any one who should refuse his assent to propositions separately proved, because when connected they may have been paradoxical, would, in many instances, be justly laughed to scorn by the masters of those sciences which make the highest pretensions to certainty and demonstration. In all these cases there is generally, in the nature of things, a limit to each of the two contrasted propositions, beyond which neither can be extended without implying the falsehood of the other, and changing the paradox into a contradiction; and the whole difficulty of perceiving the connection and agreement between such propositions arises from this circumstance, that, by some inattention of the mind, these limits are overlooked. Thus, in the case before us, we must not imagine such an arbitrary exercise of God's power over the minds and wills of subordinate agents, as should convert rational beings into mere machines, and leave the Deity charged with the follies and the crimes of men, which was the error of the Calvinists: nor must we, on the other hand, set up such a liberty of created beings, as, necessarily precluding the divine foreknowledge of human actions, should take the government of the moral world out of the hands of God, and leave him nothing to do with the noblest part of his creation, which hath been perhaps the worse error of some who have opposed the Calvinists."

We have only to remark on this passage, that had the ingenious author considered attentively the work of Jonathan Edwards on Free-will, he would not have supposed that the Calvinists hold the doctrine of necessity in the unqualified and unguarded sense which could lead to the conclusions which he has stated above. Edwards is a very high Calvinist, yet he not only rejects the pernicious consequences which are supposed to flow from necessity, but shows, with irresistible power of argument, that they do not follow from the doctrine, when judiciously and consistently explained. His work, however, seems to be but little known to philosophers, probably because it is supposed to be more intimately connected with divinity than with philosophy: it is, however, by far the most profound work that has ever been written on the question; but it is, at the same time, exceedingly dry and repulsive; and no man need attempt to read it who has not a mind capable of being delighted with naked metaphysical truth. (*g*)

MOR

MORAT, or MURTEN, is the name of a village and lake in Switzerland, in the canton of Fribourg, and on the great road from Lausanne to Berne. The town is situated on the banks of the lake. Many Roman antiquities are found in the neighbourhood, particularly at Monchwyler. In the chateau are six inscriptions, which renders it probable that this place was formerly one of the fauxbourgs of Aventicum. The village is celebrated by the battle of Morat, which was fought on the 22d June, 1476, between Charles the Bold, duke of Burgundy, and the Swiss, who routed and almost destroyed the French army. The bodies of the slaughtered Burgundians were buried in deep ditches; but four years after the battle, an ossuary, (which has been called the Charnel house of Morat,) 10 feet long, and 14 wide, was erected a quarter of a mile from Morat. In 1755, it was repaired by the cantons of Berne and Fribourg; but it was destroyed by the French army in 1798.

The lake of Morat is two leagues long, half a league wide, and twenty-seven fathoms deep; and, according to De Luc, it is about 15 feet above the level of the lake of Neufchatel. The river Broie runs from the lake of Morat to that of Neufchatel. There are many fish in the lake, and it contains a great number of the highly esteemed fish, the *Silurus Glanis* of Linnæus. See Ebel's *Manuel du Voyageur en Suisse*, tom iii. p. 524, and Cox's *Travels in Switzerland*, vol. ii. p. 157, &c.

MORAVIA is a province of the Austrian empire, including Moravia Proper and Austrian Silesia, which has been annexed to it. Moravia Proper contains 8,860 square miles, and 1,334,000 inhabitants; and Austrian Silesia 1840 square miles, and 347,000 inhabitants. The six circles of Brunn, Olmutz, Hradisch, Prerau, Znaym, and Iglau, form Moravia Proper, while Austrian Silesia is divided into the circles of Teschen and Troppau. The following is the population of the principal towns:—

Brunn	26,000	Teschen	5,400
Olmutz	11,000	Znaym	5,200
Iglau	11,000	Cremsier	3,200
Troppau	10,000	Fulneck	3,100
Sternberg	8,000	Prerau	2,900
Nikolsburg	7,600	Hradisch	1,700

Moravia is intersected by several ranges of mountains, between which are many fertile vallies; and in the north and south there are well cultivated plains of considerable extent. The principal river is the March, or Morava, which is navigable, and after receiving the Theya, runs south, and falls into the Danube above Presburg.

This province is not famous for its productions. Corn and flax are raised, but not in very great quantities. Hogs and geese are exported to a great extent. Gold and silver mines were once wrought here, but the most productive ones are those of iron and lead. Coal is found in great quantity, but the veins have not been wrought to a great extent. Fossil remains, a species of amber, and clay for tobacco pipes, are some of the other productions of the province.

The manufactures of Moravia are considerable. Woollen, cotton, and linen goods, are made to a great extent. About 40,000 pieces of woollen goods are woven annually in the neighbourhood of Iglau. The number of persons employed in Moravia in the woollen manufactory is 16,000 in weaving, and 24,000 in spinning. Thread is made at Rothwasser, and dyeing is extensively carried on at Brunn. The cotton works of Lettowitz give employment to 1000 individuals. Leather, paper, potash, and glass, are among the other manufactures of the province. The principal imports are wool, silk, flax, cotton, and oil.

The inhabitants of Moravia are Germans, Sclavonians, and Jews, of whom there are about 30,000.

MORAYSHIRE, or MURRAYSHIRE, or PROVINCE OF MORAY—a maritime county in the northern part of Scotland, bounded on the north by the Moray Firth, on the east and south-east by Banffshire, on the south and south-west by Inverness-shire, and on the west by Nairnshire and Inverness-shire. It lies between the 57° and 58° of North Latitude; and the longitude at the mouth of the Spey is 3° 6′ West, extending in length from East to West 42 miles, and in breadth 20 miles.

The county of Moray is naturally divided into the upper and champaign districts. *1st*, The low country is a large plain, bounded by the Firth of Moray on the north, and a winding range of mountains on the south, whose length equals that of the whole county, and its breadth, measured at right angles from the mountains to the shore, is from 5 to 12 miles, or mean breadth 7 miles. The surface of the low lands is diversified by intervening hills, disposed in short ridges parallel to the Firth, and intersected by the rivers Spey, Lossy, and Findhorn, whose streams wind at unequal distances. across the plain into the sea. Many of the plains along the banks of the Spey and the Findhorn are remarkable for their beauty and fertility. One-third of the bottoms and sides of the valleys within the range of the mountainous or hilly district, except certain parts adapted for bearing trees, is capable of cultivation. The width and depth of these valleys are proportionate to the largeness of the rivers, and the friability of the soil through which they flow.

The climate is so mild, that the apricot, nectarine, and peach, ripen sufficiently on a wall in the open air, and gardens are formed, and fruit trees cultivated, if the length of the lease permits the farmers to make such an arrangement. The most prevailing winds are from the west and north-west, which continue, during the year generally for the space of 260 days, and in the summer the gale is frequently from the south-west, whilst in autumn and winter it is commonly from the north-west, and often rises into a violent tempest, with rain, sleet, or snow. The heaviest and longest rains are from the north and north-west, and thunder showers and drizzling wet weather proceed from the south or south-east An easterly wind is sometimes attended with a heavy flood, and the north wind is often cold and fair, with occasionally *severe* rains. A dry parching easterly wind prevails in general towards the end of spring, blasting the corn, grass, and blossoms, through the whole district. The mean quantity of rain is 25.28 inches, or from 20.06 to 33.17 inches, during a space of nine years. The average depth of rain in the hilly districts is five or six inches greater than that on the coast. The sowing of corn continues from the 2d of March to the 10th April, and the harvest from the 28th August to November 4th. The crops are sometimes damaged in the month of August by a most destructive mildew, occasioned by vapours arising from stagnating streams, which, settling on the unripe corn, injures the milky substance in the ear, and, unless removed by brisk gales or heavy showers, blasts the hopes of the farmer. Few crops suffer from excess of rain; and no instance of any loss from this cause occurred during a period of 38 years, from 1744 to 1782. The county of Moray afforded a large supply of grain for the adjoining counties, when the very wet and cold seasons, towards the end of the sixteenth century, had produced a famine over the whole kingdom. Oat-meal was bought at that period, to be carried across the Grampian hills, at the rate of 1*l.* 10*s.* for the boil of 150 lb.

The population of Morayshire amounted, in 1755, to 13 982; in 1797, to 14,445; in 1801, to 26,705; and, in 1811, to 28,108.

The agriculture of Morayshire was not neglected during the dark ages, but mills were erected in the year 1200; carts were used, and breweries established, in 1225; and gardens formed in 1232; leases were also granted for five and three lives, in the years 1378 and 1390. The culture of wheat in Scotland was increased by an act of Parliament about 500 years ago, which compelled every farmer who had four yoke of oxen to sow one bushel of wheat; and, in 1565, James Ogilvie, of Findlater, produced on his farm 30 bolls of wheat; and the bishop of Moray had the same year, according to his rental, 10 bolls. This circumstance proves that the agriculture of Moray was in a higher state of improvement at this period than that of some of the counties in the north of England, where wheat was not introduced until more than a century after. The convulsions occasioned by the Reformation prevented the inhabitants of Moray from attending to their agriculture; and it was in such a situation, after the struggle carried on for prelacy by four successive monarchs, as to be almost wholly abandoned during the seven unfavourable seasons which took place towards the latter part of the 17th century, and the beginning of the 18th. Thousands of the inhabitants of this county perished at that time, in the high-ways and streets, in consequence of mere hunger. The magistracy of Elgin established a police for burying, every morning, the bodies of those miserable beings who had fallen victims in the streets to the famine during the night. The bier on which the dead of the adjoining parish of Urquhart were carried to their graves still remains; and it is an ascertained fact, that their ordinary attire served both for the coffin and the shroud.

The surplus oats and barley of this county are sent to Dundee or Leith, and the wheat, amounting to 8 or 10,000 quarters, to London. Salmon are sold to the extent of 25,000*l.* and other articles produce 30,000*l.* The facilities of commerce will be increased, and the navigation rendered less dangerous, by forming a harbour at Burgh-head. Woollen manufactories are established in this district, and some of the workmen are from Yorkshire. Nearly 60,000 stones of wool are carded in the counties of Moray and Nairn, and manufactured for plaiding and domestic purposes. A manufacture of cotton is also established in this county.

There are many druidical cairns, on which sacrifice was offered by the druids, about five feet high and thirty feet in circumference, surrounded with stones fixed in the ground, for preventing them from falling. There are also several mounts or motes, which were the seat on which the druids determined questions in law and property; and in Gaelic they are called *tomavoed*, or court-hill, and in the south, laws, as North Berwick Law, &c. There are also strong holds called duns and sand-hillocks, where, by means of a large fire, they summoned their warriors to repel the invading enemy. The Romans soon relinquished this province (the inhabitants of which they called Vacomagi, and its firth, Vararis,) which could neither gratify their avarice nor ambition; and on this account the only remains of their power are of a military nature. Baths, roads, and inscriptions, which belong to a tranquil age, are not to be found here. Fortified chains of communications, whose origin may be traced to a later period, extend from Burgh to the East Sea by Duffus, &c. to Garran in the Mearns. One of the most magnificent obelisks in Scotland, being 20 feet high and 4 broad, is situated nearly half a mile to the north-east of Forres. On its eastern side there are 6 divisions, whereon are represented horses with their riders, and infantry with bows and arrows, swords, and targets. In the fourth division several men armed with spears guard a number of human heads under a canopy; and in the 6th there is the appearance of horses seized, riders beheaded, and heads thrown under an arched cover. It is supposed to have been erected either as a memorial of the assassination of King Duff, or of a battle fought by King Malcolm II. of Scotland against the Danes in 1008. The ruins of the royal forts at Elgin and Forres still exist. The religious houses in this province are numerous. The cathedral at the east end of Elgin is the noblest specimen of Gothic architecture in the county. The magnificence of the building, the elegance of the sculpture, and the uniformity of the design, afford a lasting monument of the labour and ingenuity of the middle ages. Its length is 264 feet, and the height of the centre tower and spire is 198. The model resembles that of the cathedral at Litchfield, but on a larger scale, and with more ornament. The priory of Pluscardine preserves the plan of the building entire, and the whole occupies nearly 12 acres.

The Norwegians conquered Moray about the year 927, under Sigind, Earl of Orkney. Before this period the Picts occupied the Burgh, a Roman station on the Moray Firth, where they established themselves in great numbers, as appears by the ruins of the houses extending nearly two miles on the sea shore to the east. Other colonies of the same descent mingled with the British, and being driven northward by the Belgæ, Iberians, and Saxons, peopled the province of Moray. Their killing King Malcolm I. at Ulrin, the castle of Forres, and King Duffus, A. D. 966, affords a clear proof of their turbulent character. In the reign of Malcolm IV. about 1160, they rebelled, and on his attacking them submitted; but all the insurgents were transplanted into the other counties of Scotland, from Caithness to Galloway. Malcolm III. and his successors encouraged emigrants of rank from England and the continent, who acquired afterwards a considerable property, and from them many of the nobility and of the ancient families in this province are probably descended. At Forres and Mortelich battles were fought betwixt the Scots and Danes, in the year 1008 and 1010. At Speymouth, in the years 1078 and 1110, wars took place betwixt the king and the inhabitants of Morayshire. King Malcolm contended with the same people on the muir of Urquhart in the year 1160. The Frazers and M'Donalds opposed each other at Ceanlochlochie, in A. D. 1544. A contest took place between the king and the earls of Huntly and Angus, in 1594; the Covenanters attacked Montrose in 1645: and in 1690 the king's troops opposed the Highlanders.

The diocese of Moray comprehended the counties of Moray, and a great part of Banff and Inverness, which had fifty-six pastoral charges. There was an abbey at Kinloss, and the abbot had a seat in parliament. Three priories were founded at Urquhart, Pluscardine, and Kinguissie, and likewise several convents. An hospital was also erected near Elgin for entertaining strangers, and for the support of poor infirm people. The monks are said to have possessed excellent libraries. The furniture of Kinloss Abbey consisted of fifty feather beds, two silk beds, and twenty-eight arras coverings. Great hospitality marked the conduct of its inmates, with whom King Edward I. resided nearly a month and a half. The king and his attendants are reported to have drank, during this short period, the beer of more than twenty chalders of malt. Though this statement appears to be exaggerated, yet it affords a decisive proof of the good cheer in which our ancestors of the 14th century indulged.

MORBIHAN, one of the departments of the north-west region of France. It was formed out of the Bishopric of Vannes, and is bounded on the north by the department of the Cotes du Nord, on the east by that of the Lower Loire and the Ille and Vilaine, on the south-west by the Ser, and on the west by the department of Finisterre. The department is watered by the rivers Vilaine and Blavet, and produces rye, flax, cattle, horses, fish of all kinds, and has mines of lead and coal. The fertile island of Bellisle contains 5569 inhabitants. The whole department contains 358 square leagues, and 425,485 inhabitants. The following are the principal places:

	Population.
Vannes, the capital	8,728
L'Orient	19,922
Ploermel	4,512
Pontivy	3,090

The forests occupy from 37 to 38 thousand acres, the greater part of which belong to individuals. The contributions in 1803 were 2,327,248 francs.

MORDANTS. See Dyeing.

MORE, Sir Thomas, Lord High Chancellor of England, was the son of Sir John More, Knight, one of the Judges of the King's Bench. He was born in London, in the year 1480, and educated first at a school at St. Anthony's in Threadneedle Street, and afterwards at Oxford, where he soon acquired a considerable proficiency in classical learning; and being destined for the profession of the law, he came to New Inn in London, from whence, after some time, he removed to Lincoln's Inn, of which his father was a member. Having obtained a seat in parliament, he distinguished himself, in the year 1503, by his opposition to the motion for granting a subsidy and three fifteenths for the marriage of Henry VII's eldest daughter Margaret to the King of Scotland. The motion was rejected; and the king was so violently offended at this opposition, that, in revenge, he sent Mr. More's father, on a frivolous pretence, to the Tower, and obliged him to pay 100*l.* for his liberty After being called to the bar, he was appointed law reader at Furnival's Inn, which place he held about three years; and about the same time, he also read a public lecture in the church of St. Lawrence, Old Jewry, upon St. Austin's treatise *De Civitate Dei.* At one time he seems to have formed the design of becoming a Franciscan friar; but he was afterwards dissuaded from it, and married Jane, the eldest daughter of John Colt, Esq. of Newhall, in Essex. In the year 1508, he was appointed judge of the Sheriff's Court in the city of London, was made a justice of the peace, and attained great eminence at the bar. In 1516, he went to Flanders in the retinue of Bishop Tonstal and Dr. Knight, who were sent by King Henry VIII. to renew the alliance with the Archduke of Austria, afterwards Charles V. On his return to England, Cardinal Wolsey wished to engage Mr. More in the service of the crown, and offered him a pension, which he declined. It was not long, however, before he accepted the place of master of the requests. He was also created a knight, admitted a member of the privy council, and, in 1520, made treasurer of the exchequer. About this time he built a house on the banks of the Thames, at Chelsea, and married a second wife.

In the 14th year of Henry VIII. Sir Thomas More was appointed Speaker of the House of Commons, in which capacity he had the courage to oppose Wolsey, in his demand of an oppressive subsidy. Soon afterwards, however, he was made chancellor of the dutchy of Lancaster, and treated with great familiarity by the king. In the year 1526, he was sent, with Cardinal Wolsey and others, on a joint embassy to France; and, in 1529, with Bishop Tonstal to Cambray. Notwithstanding his opposition to the measures of the court, he was appointed chancellor in the following year, after the disgrace of Wolsey. In 1533, however, he resigned the seals, probably to avoid the danger of refusing his sanction to the king's divorce. He now retired to his house at Chelsea; dismissed many of his servants; sent his children, with their families, whom he seems to have maintained in his own house, to their respective homes; and spent his time in study and devotion. But he was not long permitted to enjoy tranquillity. Though now reduced to a private station, and even to indigence, his opinion of the legality of the king's marriage with Anne Boleyn, was deemed of so much importance, that various attempts were made to procure his approbation; but these having proved ineffectual, he was, along with some others, included in a bill of attainder in the House of Lords, for misprision of treason, by encouraging Elizabeth Barton, the nun of Kent, in her treasonable practices. His innocence in this affair, however, appeared so clearly, that they were obliged to strike his name out of the bill. He was then accused of other crimes, but with the same effect; until, upon refusing to take the oath enjoined by the act of supremacy, he was committed to the Tower; and, after fifteen months imprisonment, was tried at the bar of the King's Bench for high treason. The proof rested on the single evidence of Rich, the solicitor-general, whom Sir Thomas, in his defence, sufficiently discredited. The jury, however, brought him in guilty; he was condemned to suffer as a traitor, and was accordingly beheaded on Tower Hill, on the 5th of July, 1535. His body was first interred in the Tower, but was afterwards begged and obtained by his daughter Margaret, and deposited in the chancel of the church at Chelsea, where a monument, with an inscription written by himself, had been some time before erected, and is still to be seen. The same daughter also procured his head, after it had remained fourteen days upon London bridge, and placed it in a vault belonging to the Roper family, under a chapel adjoining to St. Dunstan's church in Canterbury.

Sir Thomas More was a man of considerable learning, eminent talents, and inflexible integrity. Although possessed of great sagacity in other matters, his religious bigotry exposed him to superstition and credulity. When only twenty years old, he was so devoted to monkish discipline, that he wore a hair shirt next his skin, frequently fasted, and slept upon a bare plank. Yet his disposition was cheerful, and he had an affectation of wit, which he could not restrain even upon the most serious occasions. He was the author of various books, chiefly of a polemical nature. His *Utopia* is the only performance that has survived in the esteem of the world. Hume says of him, that of all the writers of that age in England, Sir Thomas More seems to come the nearest to the character of a classical author. His English works were collected and published by order of Queen Mary, in 1557; his Latin at Basil, in 1563, and at Louvain, in 1566. A life of Sir Thomas More, by his son-in-law, Mr. Roper, of Wellhall, in Kent, was published by Mr. Hearne, at Oxford, in 1716. (*z*)

MOREA, a peninsula of a very irregular form, sometimes compared to the shape of a Mulberry-leaf, and joined to the continent by a narrow neck of land, called the Isthmus of Corinth, is situated between 36° 29′ and 38° 30′ North Latitude, and between 21° 30′, and 24° of East Longitude from Greenwich. Its greatest extent, from the Gulf of Lepanto to Cape Matapan, is about 120 miles, and its greatest breadth 110; but its coast is deeply indented by numerous gulfs, inlets, and bays. It is divided into four provinces, namely, Chiarenza, Belvidere, Tzakonia, and Romania Major. In Chiarenza, which includes all Achaia Propria, the principal places are Saraoalle, Triti, and Caminitza, which are only inconsiderable villages. In Belvidere, which contains Elis and Messenia, there are Larissa, on a river of the same name; Chiarenza, (Cyllene,) at the bottom of a gulf of that name; Tornese, a village with a castle on an eminence near a cape of the same name; Gastouni, a considerable town south from the river Peneus; Callivi (supposed to be the ancient Elis;) Belvidere, a considerable town in a delightful situation; Rofeo, near the site of the ancient Olympia; Arcadia, on the bay of the same name; Navarini, with a large commodious fort in its vicinity; Modon, a small fortified trading town, with a good harbour; Coron, a little town, well defended, near a gulf of the same name; Messene, once the capital of Messenia, now a small hamlet called Mavra-Matea, near Mount Vulcano; and Calamatia, an open town on the river Stromio. In Tzakonia, which includes Arcadia and Laconia, are Misitra, near the ruins of ancient Sparta, defended by a castle containing several public edifices; Cyparissi, (Tyros,) on the Gulf of Napoli; Malvasis-Vecchia, a little town under a strong citadel, on a small island connected with the Continent by a bridge, from the neighbourhood of which place comes an excellent wine, called Malvoisia or Malmsey; Colokythia (Gythium,) a small town on the west coast of a gulf so named; Maina, a town and district on the north of Cape Matapan, inhabited by an independent and warlike tribe, called Mainotti or Mainottes, supposed by some to be descendants of the Spartans, but who are more probably sprung from some Slavonian horde. Leondari, a village on Mount Taygetus; Trapolissa, which may be regarded the modern capital of the Morea, near the site of Tegda; Orchomenus, Phonia, and Gardena. In Romania Major, which comprehends Corinth, Sicyon, and Argos, are Corito, (Corinth) on the high ground which looks down upon the gulf of Lepanto; Vasilica (Sicyon) containing a few mean dwelling houses; Staphlica (Phlius) an inconsiderable village at the foot of mount Gromo; Vostitza (Ægium) a small place on the border of the gulf; Drepano, a village with a harbour near the promontory of the same name; Patras, a trading town containing about 4000 inhabitants, to the westward of Lepanto; Argolis, a town of considerable extent, but without any vestige of its ancient edifices; Agios, Adrianos, or Charia, (Mycene) now a small hamlet; Nemea, where there are some ruins of the ancient city of that name; Napoli di Romania, (Nauplia) a trading town, strongly fortified, with a spacious and secure harbour; Pidavra (Epidaurus) a little town in the recess of the gulf of Argos, naturally strong, provided with a tolerable port; Damala, Castri, and Hydra, places of little note, except that the inhabitants of the last mentioned are remarked as excellent sailors.

The present appearance of the Morea, as far as respects the natural features of the surface, corresponds very exactly with the description given of it in the Itinerary of Pausanias; but the country appears remarkably diminutive, when contrasted with the great events in Grecian history. The mountains of Greece are uniformly composed of limestone; and of that kind of formation which is supposed to be peculiarly liable to the phenomena of earthquakes. The valleys are vast basins, surrounded by circles of these mountains, and the country is thus divided into a number of distinct craters, each of which contains a spacious level area, naturally fitted for a separate community. Its surface is compared by Dr. Clarke to a number of saucers with broken lips, placed together on a table. Excepting the Pamesus, Cephisus, and Eurotas, the rivers of the Morea are exhausted; and are nothing more than little streams, with almost dry channels in summer, but rapid torrents in winter.

There are no Greek or Roman roads perceivable in the Morea: but only Turkish causeways about two feet and a half in breadth, leading over the low marshy spots; and these are sufficient for the horses of the soldiery, or the asses of the peasantry, who rarely make use of any wheel carriages.

The climate, and the whole aspect of nature in the Morea, presents a harmonious uniformity, softness, and repose, and the scenery is often beautiful. The soil in the valleys is fruitful, and susceptible of every species of culture; and the mountains are covered with pasture and medicinal herbs; but only a few of them, particularly Helicon, are adorned with luxuriant shrubs, and covered with thriving flocks. Rose-laurels, and the Agnus Castus, with its long, pale, narrow leaf, and purple woolly flower, are met with all over the country; and are almost the only decorations of its now solitary wastes.

It would be a vain attempt to describe the remains of ancient arts and architecture in modern Greece; where every species of destruction follows another so rapidly, that frequently one traveller can discover no trace of the monuments which another had admired but a few months before.

The population of the Morea has been estimated by some at 300,000, but the following is one of the most recent computations, namely,

400,000	Greeks.
15,000	Turks.
4,000	Jews.
4,000	Mainottes.
423,000.	

The history of this country, from the dissolution of the Achaian league, B. C. 146, is connected with that of Rome; and, after the fall of that empire, is to be sought in that of Venice and Turkey. We notice, at present, only a few of the leading events in its state and history, from the conclusion of its ancient annals, given under the article GREECE, in this work. In the civil wars of Rome, the Athenians espoused the cause of Pompey, which they considered as that of liberty; while the Spartans adhered to the interests of Cæsar, and fought against Brutus at Philippi. Vespasian reduced Achaia to a Roman province, A. D. 79. The laws of Lycurgus were still in force at Lacedæmon in the reign of Domitian, A. D. 91. Adrian, A. D. 134, rebuilt the fallen monuments of Athens, erected a new city in the vicinity of the ancient one, and revived throughout Greece the reign of science and the arts. Under the Antonines the schools of Athens were restored to their former splendour; and the city swarmed with a multitude of philosophers, and their respective disciples. Sparta had fallen into obscurity, except that the emperor Caracalla chose a band of her citizens as his body-guard. In the year 261, the Heruli pillaged the greater part of the Morea, and eight years afterwards, Athens was taken by the Goths, but rescued from their hands by one of its citizens named Cleodemus. In 395, the whole of Peloponnesus fell under the successive ravages of the barbarians; and its devastation was completed by the troops under Stilico, who marched to its deliverance. Justinian made some attempts to repair its ruins; and, when the eastern empire was divided into governments called *Themata*, Lacedæmon became a domain of the brothers, or eldest sons of the emperor, who assumed the title of Despots. From this period, A D. 527, there are few historical records of this renowned region, for the long space of 700 years. In 846, Greece was overrun by the Sclavonians, who are supposed to be the ancestors of the modern Mainottes; and, in 1081, the western coasts were ravaged by the Turks. About the beginning of the 12th century, the Venetians and other western nations invaded the Peloponnesus, which appears, about this time, to have changed its name for that of the Morea, in consequence (as is conjectured) of its abounding in mulberry trees, which then began to be extensively cultivated in the growing manufacture of silk in the country In the commencement of the 13th century, Boniface, Marquis of Montserrat, joined by other bands of Crusaders, reduced the whole of the Morea, which was soon after given up to the Venetians by the terms of a general treaty concluded at Constantinople. Occasionally possessed by different chiefs, called princes of the Morea, it was for 57 years the subject of contention between the Latin emperors of the East, and the Greek emperors who had retired into Asia. Occupied at different times, for short periods, by various adventurers, it fell at length, in the beginning of the 15th century, under the power of the Mussulmans. It was reconquered by the Venetians in 1688, and retained by them till 1715, when it reverted again to the Ottoman empire. In 1770, a last and unavailing attempt was made by its inhabitants, at the instigation of Catharine II. of Russia, to throw off the Mahometan yoke; but the Turkish oppressions have since that period increased in severity, and nothing can exceed the present wretched degradation of the once celebrated people who inhabited the plains of Peloponnesus.

But modern Greece, so long forgotten in history, and obliterated from the list of nations, has attained, in these later ages, a new species of renown; and has become the resort of the learned and ingenious from every land, by the mere attraction of its monumental remains. As soon as the nations of Europe were roused from their barbarism, their attention was directed to the cities of the Morea, as the repository of all that survived of ancient art and ornament. So early as the year 1465, Francesco Gambietti made drawings on vellum of many of these Grecian monuments, which were deposited in the Barberini library at Rome, and which are the more curious and valuable, as they were taken when these structures were still entire. In 1550, Nicholas Gerbel published at Basil a description of Greece. In 1584, Martin Crusius, professor of Greek and Latin in the university of Tubingen, in a work entitled Turco-Græcio, gave an account of Greece from the year 1444 to the time in which he wrote. About the beginning of the 17th century, the establishment of French consuls in Attica, and about 50 years afterwards, the arrival of the Jesuit missonaries from the same country, contributed to enlarge the knowledge of Grecian monuments in the Morea. De Monceaux, who visited Greece in 1668, described antiquities, of which not a vestige now remains; and Father Babin, published, in 1672, the most complete and circumstantial account of the city of Athens which had then appeared. But the travels of Ipion and Wheeler, in 1678, presented the ablest view that had been given, in modern times, of Grecian arts and antiquities. At the same time the earl of Winchelsea conveyed several fragments of Grecian sculpture to England; and Vernon, an English traveller, published a rapid sketch of his travels in Greece in the Philosophical Transactions. From this date the travellers in Greece found only the ruins of many of the finest monuments hitherto described by their predecessors, in consequence of the ravages committed by the Venetians in their reconquest of the Morea. In 1728 the Abbé Fourmont was sent to the Levant in quest of inscriptions and monuments, but his work was never published; and Pococke, in 1739, gave one of the most accurate descriptions that had yet been made of Grecian ruins. In 1758, the picturesque tour of Greece by Leroi, a French artist, and, 1761, the more correct views published in Stuart's Antiquities of Athens, made great additions to the topography of modern Greece; but the work of Chandler, a few years afterwards, rendered almost every other account superfluous. During the Russian invasion in 1770, many of the remaining monuments in the Morea were demolished, and succeeding travellers began soon after to carry away every portable fragment of Grecian art, as the only mode of preserving them from more barbarous destroyers. Baron Reidesel in 1773, M. de Choiseul in 1778, Foucherot and Fauvel in 1780, still found something new in addition to former descriptions. The travels of M. Scrofani in 1794, and the works of Pouqueville, who describes however what he did not visit, have rendered modern Greece more fully known in many points of considerable importance; but the numerous researches of English travellers, in every corner of Grecian territory, have furnished a mass of intelligence, which cannot be brought within the compass of an article like the present; and to which we must refer our readers for the fullest information on the subjects so briefly noticed in the following paragraphs.

A few Greek families pretend to trace their descent from the distinguished names who once stood at the head of the Byzantine empire; and are considered as forming a class of Grecian nobility at the present day. To these the Ottoman court has granted four dignities, or high offices, which are a perpetual object of ardent competition among them, and in which they are incessantly intriguing how to supplant one another. These are, the Patriarchate of Constantinople, the office of Dragoman, or chief interpreter to the Porte, and the governments of Moldavia and Wallachia. The first is always procured by simoniacal purchase; the second generally in the same way. The person who enjoys it has the opportunity of recommending to various posts of honour and profit, and receives a due remuneration for every exertion of his influence. The two last, which are commonly bestowed upon the Dragoman, as a reward of his services, are held at the pleasure of the Sultan, and are seldom enjoyed above three years; during which period the Waivodes of these provinces levy great sums by the most arbitrary exactions. However short a period any individual has possessed one of these three secular offices, he retains afterwards the title of prince, with the privilege of wearing yellow slippers, and riding on horseback. In the Morea, the municipal government of certain districts is conferred upon native Greeks, who are entitled Codja Bashees, and who affect considerable state, as well as maintain a numerous household. They have their physician, secretary, assistant clerk, courier, five or six chaplains, and several servants in every department, to the number altogether of 40 or 50 dependents. They are too generally more oppressive and domineering to their countrymen, than even their Turkish masters. The modern Greeks are completely sensible of their degraded state; and discover a strong attachment to their country, as well as an ardent desire of political emancipation. Their ideas, however, go no farther back than the days of the Greek emperors; and they have no view of establishing any independent republics like those of ancient Greece. Their hopes are solely directed to the restoration of the Byzantine kingdom, in the person of any Christian prince, but, particularly one of their own church. For more than half a century they have naturally turned their views towards Russia; but two desperate attempts, in conjunction with the troops of that nation, one in 1770, and another in 1790, proved completely unsuccessful. During the expedition of the French to Egypt, they began to cherish the hopes of liberty through their means; and were ready to have joined their standard in the invasion of Turkey. They made similar advances to the British, during their short war with the Porte in 1807; but, besides receiving no encouragement from the British authorities, they consider them as too distant allies; and still look to the Russians and French as their natural deliverers. Without such foreign aid, they are utterly incapable of asserting their independence. The whole nation is not computed to exceed two millions and a half of all ages and sexes; and even these are so mixed a race, that they are rather a Christian sect, than a distinct people. It is chiefly by means of their marine, that they may regain some weight among other nations; and the establishment of some Christain power in the islands of the Archipelago has long been considered as the likeliest step to the improvement of the Greeks. The French, in consequence of employing only Frenchmen as agents and consuls in the Levant, with good salaries, have the greatest influence with the natives, and it is worthy of consideration how far the interests of Great Britain might not be extended by a similar plan, and by cultivating a close intercourse with the modern inhabitants of Greece and its islands.

The commerce of the Morea, and of modern Greece in general, is greatly fettered by the restraints of the Ottoman government. The Greeks have a flag for their merchant vessels, but not being an independent people, it is little respected by other nations; and their Turkish masters, who are jealous of their power, seldom resent any insult offered to them at sea. They are not permitted to trade farther west than Tunis, Malta, and Messina; and the Algerine corsairs are permitted, by treaty with the Grand Seignior, to capture any of his Grecian subjects who may be found trading to the westward of these ports. Thus unprotected and exposed, they are apt to seek redress at their own hands; and, when insulted by any vessel of superior force, they retaliate cruelly upon any inferior ship belonging to the same nation which may fall in their way. The Morea produces a great variety of articles which are valuable in commerce; and many of them such as are in great request in the British market. Dried fruits of various kinds, almonds, small nuts, gums, galls, and a variety of drugs, are very common articles of traffic. But the larger and more valuable commodities which the country affords, are currants, which are larger and cleaner than those of most other countries, and of which eight millions of pounds weight are said to be annually exported, usually at three halfpence per lb. English; young fustic, a valuable dye wood for bright yellow; cotton in considerable quantities, but rather of an inferior quality; olive oil of a tolerably good quality, and much cheaper than that of Italy and Sicily, generally at £25 per ton; valonia, a kind of acorn used in tanning, and much in demand by the English; corn, wool, silk, carpets, leather, vermilion, wine, wax, cheese, are frequent articles of export.

The articles of import generally carried to the Levant, are watches, jewellery, glass, porcelain, furs, spices, coffee, sugar, indigo, cochineal, sulphur, silk, gold-lace, cloth, muslins, hardware, and other manufactured goods of England and France. The balance of trade is alleged to be one-fifth in favour of the Morea, which is paid in silver coin. Of this amount, two millions of piastres go as tribute to Constantinople; one million is taken by the Pasha of Tripolizza; and the remainder, about 1,093,750 piastres, is the profit of the rich Greeks. The Frank residents are only a sort of brokers, who have a per centage upon the traffic.

The Greeks are universally addicted to commerce, and their marine is in many respects highly important. The islanders form the most enterprising portion of the nation, and carry on a petty trade in numberless half-decked boats, with high stems and sterns, and one thick short mast, with a long yard. They perform these voyages, even as far as Smyrna and Constantinople, without chart or compass, and merely, as of old, by the observation of coasts and headlands. But they are acquainted with the management of the largest vessels of European construction; and, besides navigating the Ottoman navy as seamen, they have large merchant ships of their own, which trade as far as America and the West Indies, and make an occasional voyage to England. The natives of Hydra particularly, the most expert of the Greek mariners, have accumulated great wealth by their commerce, and have purchased from the Turks the independent election of their own magistrates. The number of Greek mariners actually employed at sea, is supposed to be not less than 50,000; and they are considered as capable of being trained to any kind of naval service.

Though the modern Greeks are very ignorant, they are a very ingenious people; and, if rescued from oppression, might again distinguish themselves in the arts and sciences. But, since the 12th century, they have made no improvements, and transmitted no inventions to other nations. Their ancient authors had long lain neglected in monasteries and libraries; their late writers were rather expert grammarians than original authors; and the revival of their literature, in the 14th and 15th centuries, was more owing to the exertions of the Italian literati than of native Greeks. The corruption of the Greek language has been dated from the time of the Macedonian conquest, and is particularly ascribed to the extension of the Roman power; but it appears to have survived as a living language in considerable purity so late as the 11th or 12th centuries. The irruption of the Goths and other barbarians, and the settlement of the Sclavonians and Franks in Greece, occasioned numerous corruptions, about the beginning of the 13th century; and the establishment of the Ottoman empire introduced many Turkish terms and idioms; but it is not possible to fix the precise period when the distinction between the Hellenic or ancient, and the Romaic or modern dialect, was generally acknowledged. It appears that a multitude of different dialects prevailed in the progress of its corruptions, not less, it is said, than seventy; and that the Romaic did not become an established language till about a century after the Turkish conquest. The first instance of it, as a written language, is a translation of the four apologies of John Catacuzenus into the vulgar tongue by Meletius Syrigus, a Cretan, who died in 1662. The earliest and best of the grammars of this new language is that of Portius, also a native of Crete, which may be seen in the glossary of Du Cange. Besides the introduction of new vocables, the modern dialect drops the inverted arrangement of the words, forms the tenses by the aid of the auxiliary verb, and makes great use of the contractions, so as to blend several words into one. The pronunciation unquestionably became vitiated along with the structure of the language; but the Byzantine Greeks maintain that they still possess the ancient mode of reading it. A sketch of the modern dialect, and of its pronunciation, may be seen in the appendix to *Hobhouse's Travels*, and Dalaway's *Description of the Levant*; but the following specimen of the mode of reading the first lines of Homer, as given by the former writer, may give some idea of the modern pronunciation. The *a* is to be sounded as in the English word *plate*:

Mēnin āedthe Thea Peleiādtheo akelaos
Oolomānen ē merē akœēs ālge ātheke
Pollās d'ipthēmoos psekās āedthe proeāpsen
Erōone, aftoōs dē elōrea tēvke kēnessin
Æonæse te pāse. Dtheōse d'eteléeto voolē.

There are great varieties, however, in the mode of speaking the Romaic. The Greeks of the Morea and on the coasts of the Adriatic, intermix more of the Venetian; and those of the Archipelago or Smyrna, more of the Turkish; while those of the Fanal, in Constantinople, speak it in the most classical style of purity.

Since the establishment of the Romaic, the Greek literature has been extremely limited; and in the course of 150 years previous to the year 1720, about 100 persons have been recorded as men of learning, the greater part of whom, as well as of the later writers, were theological authors, educated in Italy. But, in consequence of the recent communications between the more enlightened nations of Christendom and the Levant, considerable improvements have taken place. About the end of the last century, under the auspices of a prince of the family of Mavro Kordato, who was Hospodar of Moldavia, a dictionary and grammar of the Romaic was published, and several translations of French and Italian novels, printed in that language at Venice or Vienna. A few of the higher Greeks compose pieces in poetry, but rarely for publication; and there is little original composition yet produced among them. Numbers, however, attend the universities of the Continent, chiefly from the Ionian isles; a few of them for the sake of ecclesiastical studies, but most of them for the purpose of qualifying themselves to practice as physicians in their own country. The principal study of the modern Greeks is the acquisition of languages, in which they display a wonderful proficiency; so that many of their young men are able to speak five or six languages at a very early age; and numbers of the lower orders can make themselves understood in French, Italian, Russian, Turkish, Sclavonian, and Latin. A Greek printing press has been established at Bucharest, and another at Venice, for a considerable period; but grammars, dictionaries, theological tracts, vulgar romances, and song books, are the only productions of these establishments. A few learned Greeks in Paris have distinguished themselves by their talents, and have published several translations in Romaic for the benefit of their countrymen; but not more than one or two native authors are known at present to reside in Greece. The principal Romaic books to be found there, are translations of Beccaria *On Crimes*, Locke's Essay, Montesquieu's *Rise and Fall of the Roman Empire*, Rollins's *Ancient History*, Telemachus, *Plurality of Worlds*, Goldsmith's *Grecian History*, *Robinson Crusoe*, the *Arabian Knights*, an original *Life of Suvaroff* by a merchant in Athens, and a journal printed at Vienna, besides the ordinary catechisms and homilies of the church. But there are no shops for purchasing books, and scarcely any thing like a library, public or private, in the country. There is no dissemination of knowledge among the natives of Greece, except by means of one or two schools in some of the larger towns, where the ancient Greek, and sometimes Latin, with the modern languages, are taught. Most of them can read and write, so as to be qualified for the service of their pashas, and the transactions of their petty commerce, but have no knowledge of books, or attainments in science. They can all compose a song or lampoon; but their best productions have more of the oriental imagery than the Greek simplicity; and all their poetry is full of the worst kind of taste. Their prose writings are insipid, and chiefly distinguished by copiousness of words.

The state of the arts in Greece is very low; and it is said, that there is not a sculptor, painter, or architect to be found, equal to the common workmen in the towns of Christendom. Their paintings are chiefly gilded saints; and the best are to be seen at Scio.

Medicine is practised by Italians, or by native Greeks, who have received some education in Italy; or even by persons of no education, but who, having failed in other pursuits, put on the Frank habit, and assume the office of physicians. In most of the towns there is at least one of these persons, who is paid so much per annum for taking care of the health of the whole inhabitants. The general practice is, to administer jalap, manna, glauber salts in small quantities, draughts of bark in almost every complaint, allowing the patient at the same time plenty of fat broths. Phlebotomy is often used, but not topical bleedings. When the disease is of long continuance, or if the least delirium appears, the patient is considered as possessed; and instead of the physician, the priest is employed to exorcise the evil spirit. Pestilential fevers, elephantiasis, leprosy, and the plague, are seldom attempted to be cured by medical skill. The frequent use of the warm bath, to which the natives are much addicted, is probably more prejudicial than salutary to their health.

The Greek music is plaintive, but very monotonous; and it is doubtful whether most of their airs may not be of modern origin. They sing through the nose, and in a confused manner, men and women all joining together. Of many tunes borrowed from the French and Italian, it is said they never go beyond the first part. "They have an admirable *kyrie eleison*," says Chateaubriand. "It is but one note, kept up by different voices, some bas and some treble, executing *andante* and *mezza voce*, the octave, the fifth, and the third. The solemn and majestic effect of this *kyrie* is surprising. It is doubtless a relic of the ancient singing of the primitive church." The fiddle and lyre, or three-stringed guitar, are the usual instruments upon which most of the young men, and particularly the sailors, are able to perform. Pan's pipe, and a kind of bagpipe, are also met with in the Levant. Modern travellers give a very unfavourable account of the general strain of music in Greece; Dr. Clarke, particularly, represents it as inferior to that of any other European nation, except the very lowest in point of civilization and refinement. "The tone of the vocal part," he says, of a certain performer, "resembled rather the howling of dogs through the night, than any sound which might be called musical. And this was the impression made upon us every where by the national music of the modern Greeks, that if a scale were formed for comparing it with the state of music in other European nations, it would fall below every other, excepting only that of the Laplanders, to which, nevertheless, it bears some resemblance."

There is a considerable resemblance in the doctrines and general form of the Greek church, and those of the church of Rome. In the number of the sacraments, the invocation of saints, the belief of the real presence, the practice of auricular confession, the offering of masses for the dead, the division of the clergy into regular and secular, the spiritual jurisdiction of the bishops and their officials, the distinction of ranks and offices among the ecclesiastics, there is very little difference between the churches of Greece and Rome. This resemblance is kept up and increased, in consequence of the number of Greek ecclesiastics who study in Italy; and, in the Morea and Archipelago, there are many Roman Catholic converts among the natives. The Greek clergy are divided into two classes, the Papades, or secular priests, who hold the parishes, and the Caloyers, or monks of St. Basil, who have their seminaries on Mount Athos, in Chios, and the Prince's Islands. The secular priests, contrary to the case in the church of Rome, are the most ignorant and illiterate, while the monks are generally men of a certain degree of education. All orders of the seculars, inferior to bishops, are permitted to marry, provided they choose a virgin, and engage before ordination; but can never rise higher than to the office of proto-papa in the church where they serve. All who aim at a mitre must observe celibacy, and assume the monastic habits.

The parish papas enter into priest's orders by a kind of public election. Being proposed to the congregation or church, the officiating priest asks the audience if he is worthy, and upon their acclamation in the affirmative, he is considered as authorised to enter upon his functions. The chapels, which are very numerous, and some of them little better than a cavern with a door and stone altar, must have each their own priest, who cannot officiate in other places of worship, and who, though more serviceable than the monks, are not so well provided for.

The Caloyers never say mass, and if they take the priesthood, they are called "holy monks," and officiate only on high festivals.* Admission to the brotherhood is obtained by paying to one of these holy monks a sum of 60 or 70 piastres, without any probation or examination, so that young children are allowed to take the habit, as they thus secure, in their miserable country, the certainty of being fed. Their monasteries are frequent objects in the valleys, forests, and hill-sides; and they have farms tenanted by one of their order, in most parts of the country. They subsist partly by the lands attached to the monasteries, and partly by the voluntary contributions of the people. On particular days, they go about with little pictures of their saints, which they give their votaries to kiss, and a jar of holy water with a brush, by which they mark the cross on the foreheads of each person, receiving a para or two from every individual for this service. They abstain wholly from flesh, and observe a very austere mode of living. Most of their time is occupied in a set of superstitious devotional exercises, reciting parts of the Psalter, or bowing and kissing the ground for a certain number of times. Three hundred of these bowings must be performed by each individual in every 24 hours. Their ignorance and simplicity is extreme, and in few of their monasteries have they any books, not even any part of the Scriptures. The most sacred of the Caloyers are those who have received their education in the seminaries of Mount Athos, where there are six thousand of the order, who occupy themselves in studying and in all kinds of mechanical trades. There is no ground for the charge of these monasteries being the abodes of vice. The head of the church is the Patriarch of Constantinople, whom they style the thirteenth apostle, but to whom they attach no personal sanctity or official infallibility. The person admittted to the office is invested in a triumphal mannner by a minister of the Porte; and possesses a kind of absolute authority over the whole native Greeks. His influence with the Sultan is very great, and his applications are generally effectual in every thing relating to his own nation. He can bring any Greek to be punished by fine, deposition from office, imprisonment for life, banishment, or death. This dignity is now regularly exposed to sale, and costs about 60,000 crowns. The Patriarch indemnifies himself by selling the other patriarchates of Jerusalem, Antioch, and Alexandria, besides all the archbishopricks, and every lucrative place within his jurisdiction; a practice which the Greeks themselves introduced, by offering to fill these offices for smaller salaries, or by giving for them greater sums, when vacant. The whole of the Patriarch's usual revenue does not exceed £3,000; (except what fines and extortions may yield,) and the richest bishops do not possess more than £300 a year, which is raised by a direct tax upon every Greek house within their districts. Contributions are made by devout individuals to assist those who make pilgrimages to the holy sepulchre at Jerusalem, and who are afterwards distinguished by the name of "hadje," as among the Turks. The clergy in general have great influence over the people; and receive, on certain days, gifts of loaves, sweet meats, wax tapers, &c.

The rites of the Greek church are in themselves very absurd, and are performed with very little solemnity. There are prayers and portions of scripture, histories of the saints, hymns, and forms for different festivals; but the service consists principally in singing, without musical instruments. In the celebration of the mass, the chief part of the worship consists in crossing and repeating a thousand times, in a combined song, the words, "Lord have mercy upon me." Pictures are admitted into the churches; and great attention paid to the form and colour of the clerical vestments. Their festivals are very numerous, which the people are strictly enjoined to observe: and as most of them are celebrated by dancing and music, they are the great delight of the frivolous natives, under their present oppressions. The sacrament of the eucharist is administered to new born infants, and that of extreme unction is not confined to the dying, but is given to devout persons upon the slightest malady, and even to those who are in full health, by way of anticipation. The laity are devoutly attached to all the ceremonies and ordinances of their church, which are numerous and severe. Wednesdays and Fridays are days of fasting throughout the whole year; and some of the principal fasts, such as Easter and Christmas, continue forty days; so that there are not above 139 days of the year free from all fasts. They are devoted to superstitions, which occupy their minds infinitely more than the great points of their faith. The priests are frequently employed to exorcise persons supposed to be possessed by evil spirits. They all believe in the power of magic, and often fancy themselves to be suffering from the incantations of some malevolent being. Ghosts or fairies, called Arabins, are imagined to haunt houses and other places. They believe in the occasional appearances of angels to make particular revelations. They are all devoted to the worship of the holy virgin; and in al-

* Caloyer is supposed to have been a name of the Grecian priests long before the introduction of Christianity, and to be derived from the words καλὸς ἱερεύς, the "good priest," or καλογεροι, "good old fathers."

most every cottage, her picture or image is to be seen, with a lamp burning before it. Almost all diseases are considered as the effects of demoniacal influence; and the plague particularly is thought to appear in the form of a lame and withered hag.

The churches in Greece have great simplicity; and are generally very small. The floor is of mud, the altar of stone, the sanctuary separated from the nave by deal boards, and an enclosure of pales at the other end made for the women. They are seldom furnished with seats; here there are several crotches in one corner, upon which the aged worshippers support themselves. In the greater towns, and in some of the monasteries, they are fitted up in a better style, but in a bad taste, ornamented with gildings and pictures of saints.

The modern Greeks bear a great resemblance to the descriptions which have been transmitted of the ancient inhabitants of the country, in their bodily appearance, dress, diet, and tempers. There is a national likeness observable among them all, but the islanders are of a darker complexion, and a stronger make, than those of the main land. Their countenances are such as may be supposed to have served for models to their ancient sculptors; and the young men particularly are distinguished by a degree of beauty which would be considered as too effeminate among those of the same age in more northern climates. Their eyes are large and dark, their eye-brows arched, their complexions brown, but clear, and their cheeks and lips tinged with bright vermilion colour. Their faces are a regular oval, and their features perfectly proportioned, except that their ears are rather larger than usual. Their hair is dark and long, but shaved off in the forepart of the crown and sides of the face. Beards are worn only by the clergy and persons of authority, but all of them wear thin long black mustachios on the upper lip. Their necks are long, but broad, and well set, their chests wide and open, their shoulders strong, but their waists rather slender, and their legs large, but well made. Their stature is above the middle size, and their form muscular and round, but not corpulent. The women are inferior to the men, both in face and figure; and though they have the same kind of features, yet their eyes are languid and their complexions pale, their whole persons loose and flaccid, their height rather low, and their forms, as they advance a little in life, fat and unwieldy. Those of the better class are very careful to improve their beauty by paints and washes; but they often lay on their colouring substances to a very unnatural degree.

The dress of the modern Greeks bears a near resemblance to that of the Turks. The under garments are a cotton shirt, cotton drawers, a vest and jacket of silk or stuff, a pair of large loose trowsers drawn up a little above the ancle, and a short sock. Over these are worn large shawls, often richly ornamented, wrapped round the loins, in one corner of which the poorer people frequently conceal their money, and a loose gown or pelisse, with wide sleeves, which, in the presence of a superior, they wrap modestly about their persons, concealing their hands with the sleeves, and resting their chins on their bosoms. The wealthy individuals have pelisses of cloth lined with fur for winter, and who wear purses, which, together with handkerchiefs, watches, snuff-boxes, papers, they carry in their bosom between the folds of the vests, and count it a mark of distinction to have this part of their dress full and distended. They may wear any colour except green, which is appropriated to the descendants of Mahomet, and, instead of a turban, they have a large calpac. The common people seldom use a gown, and have their trowsers so short as to leave their legs bare below the knee. The sailors have nothing but a jacket; and in summer wear the Albanian red scull-cap. The dress of the females bears some resemblance to that of European women, and consists of a vest fitting close to the bosom, but becoming larger and wider below the waist; a gown flowing off loosely behind, with long wide sleeves turned up at the wrist; a ribbon or other girdle under the bosom, a rich shawl, as a zone, wrapped once round the body, resting loosely on the hips, and fastened before with a large plate, or tied in a spreading knot. The dress of the richer females is loaded with gold and silver trimmings, bracelets of precious stones, and strings of gold coins round their necks. The young women have their hair hanging down the back, loose or plaited, combed over the forehead and the sides of the cheeks, and a little red cap, with a gold tassel studded with zequins, on the one side of the crown. When they go abroad, they are muffled up in a wrapping-cloak, with a long veil, but in their private apartments they have their feet naked, and their bodies thinly clothed, as the temperature of the weather may admit. Their toe-nails and finger-tops are stained of a rosy colour, and their eye-lashes with black. No change as to fashion takes place in their dress, but their habits are esteemed entirely in proportion to the price which they cost. The most universal part of Grecian dress, which is also worn by all the inhabitants of the Levant, Mahometans or Christians, males or females, and the sale of which forms a principal article of Grecian commerce, is the ancient Pelasgic bonnet, shaped like a scalp, which the natives of Greece are said to have worn ever since they were known as a people. The Greeks wear it simply as a hat; the Turks surround it with a turban; and the women adorn it with a handkerchief, tassels, and fringes.

The diet of the modern Greeks, even in the higher ranks of society, is very poor and comfortless. Fowls newly killed, and therefore tough, though boiled down to rags, heaped together in a large plate, form a principal dish at dinner. The table is a low stool, and the guests are seated round it on cushions. A long, coarse, narrow towel is spread over the knees of the party at table; and the master of the house, stripping his arms bare, by turning up the sleeves of his tunic, serves out the soup and meat, tearing the poultry and butcher-meat into pieces with his fingers, which the guests eat in the same style. If knives and spoons are used, they are never changed, and one dish only is placed on the table at the same time. Brandy is handed to the company before they sit down to table, and a single glass of wine is presented to each along with the desert. During the time of dinner the room is filled with a multitude of visitors, meaner dependants, and even slaves, who do not partake of the repast, but sit and converse together behind the party at table; and after dinner an itinerant songster pushes through the crowd to a conspicuous place in the apartment, and accompanies with his lyre some miserable recitative, suited to the occasion, or some common love-ditty, repeated again and again with little melody or expression. When the meal is concluded, a maid-servant sweeps the carpet; and the master and mistress of the house, seating themselves at the upper end of the divan or couch (which is universally placed in the form of the Greek letter Π,) the rest of the company are marshalled on either side in two lines, according to the rules of precedence. When all are thus seated cross-legged, a little pewter basin is placed before each person who had partaken of the meal, and all wash their hands and mouth with a lather of soap; the same having been done also before eating. Tobacco-pipes are then brought in, and female visitants arriving, the mistress of the house retires with the women who are present, to receive these new guests in another apartment.

In the inland towns, the women live in a separate part of the house, and are nearly as much confined as those of the Turks. Before marriage, they are rarely seen by any male person, except those of their own family; but, afterwards, they are introduced to people of their own nation, or to travellers. They can seldom read or write, but are all able to embroider, and generally to play on the lute. Dancing is an universal accomplishment, and is learned from one another here in a style which displays neither elegance nor liveliness, and which chiefly consists in a solemn poising of the body on one foot, then on the other, accompanied by various elevations and depressions of the arms. But, notwithstanding their want of education, most of them are acquainted with a number of songs or recitations, accompanied with tales, which are taken up and continued, apparently without end, by different individuals of the party for hours together. Whenever they have an opportunity of making farther attainments, they discover great quickness of understanding, and readily acquire the modern languages, and the elements of general literature. Their character is described as amiable, and they make assiduous housewives and tender mothers.

The dances of the young women, particularly those called Romaica, consists in slow movements, in which they hold by each other's handkerchiefs, while one of them, as a leader, sets the step and the time. In their mixed dances, a male and female are alternately linked together, holding their handkerchiefs high over their heads, while the leader dances through them; and various figures are performed as well as single hornpipes. Single performers among the men exhibit frequently a rapid and fantastic step, which is considered as the ancient pyrrhic dance. To such amusements the natives are greatly devoted; and, "amidst all their poverty and oppression," says Sandys, "they will dance whilst their legs will bear them, and sing till they grow hoarse." There is an ancient dance, much in request, performed by boys or by girls in the harems for the entertainment of the Turks, and which is wholly of a lascivious tendency. Nay, in most parts of modern Greece, these indecent attitudes, which are esteemed as the highest accomplishment of the art, are practised by the most discreet females, without any appearance of depraved feelings on their part.

In the marriage ceremony, which is considered as still resembling the ancient usages, the bride and bridegroom stand near the altar, holding a lighted candle in their hands, while the priest, facing them, reads and sings a service, during the progress of which he takes two rings, which he puts upon their fingers, and two garlands, which he places on their heads, changing them several times with great rapidity, gabbling and singing all the time, till at last the rings are left on the proper fingers, and the garlands laid aside together. Some bread, which has been blessed and marked with the sign of the cross, is then broken and eaten by the bride and bridegroom, and a cup of wine is presented to them successively; after which the woman hands round the cake and liquor to the persons present, from whom, if she is not of high rank, she receives a piece of money, and kisses their hands in return. On the same, or sometimes the following day, she is carried in procession to her husband's house, and the evening is concluded with music, dancing, and a feast, chiefly of fruits, and particularly nuts.

The Greeks are remarkable for the formality and tediousness of their salutations. When two of them meet, however casually, they stand with their hands on their hearts, bowing gently for five minutes together, inquiring after each other's healths, their wives, daughters, sons, family, and affairs, twenty times over, before they begin to converse, or even when they are intending to separate immediately.

The modern Greeks are full of superstitious practices and unmeaning usages, many of which they have communicated to their Turkish conquerors. During the birth of a child, the lamp burns before the picture of the virgin, and the cradle is adorned with handkerchiefs and trinkets, as presents to the fairies. As soon as the infant is laid in the cradle, it is loaded with amulets: and a bit of soft mud, particularly prepared by various charms, is stuck upon the forehead, to prevent the effects of the evil eye. When a stranger looks intensely upon a child, the mother spits in its face, or in her own bosom, if he look at herself; but the sovereign remedy against the evil eye is the use of garlic, or even the pronouncing of the name of it, and bunches of it are attached to new built houses and vessels. When a person sneezes in company, the conversation is stopped, and all present pronounce benedictions on him, at the same time crossing themselves. They wear rings as spells; observe all manner of lucky and unlucky days; spit into their own bosoms upon any sudden emergency; show a peculiar veneration for salt, and practise a multitude of divining ceremonies on all occasions.

The funerals of the Greeks, like those of their ancestors, are celebrated as occasions for various entertainments, and in some respects bear a considerable resemblance to those of the lower Irish. On the death of any person of dignity, the body is dressed in a rich garment, and the litter covered with flowers. The friends and domestics, with the priests, walk in procession before the body, and a few old women, on each side of the bier, continue howling and lamenting, enumerating the virtues of the deceased, and dwelling on the many reasons which should have made him remain longer in life. Behind the body come the female relations and friends, muffled up in mourning habits. At the place of interment a funeral service is read, and the body, rolled in a winding sheet, is deposited in the grave with some of the flowers that had adorned the bier. About the ninth day after the funeral, a feast is prepared by the nearest relation, who makes presents to the priests, and entertains the guests with music, dancing, and every kind of merriment. The burying grounds are at a distance from the towns, and the churches are generally near the high road. Their groves of cypress or yew trees generally surround the tombs; and these spots are frequented on certain days by the relatives of the recent dead, who, after shedding a few tears, and depositing a garland, or lock of hair, in the grave, spend the remainder of the day in dancing and singing.

The character of the modern Greeks is variously represented; but the greater number of travellers concur in the principal features of the following portrait. Their manners are very engaging, but have rather too much the appearance of obsequiousness and insincerity. They are extremely courteous towards inferiors, and even servants; and make very little distinction in their behaviour to each other on account of rank. The rich are versatile and intriguing; the lower classes full of merriment, doing nothing at certain seasons but pipe and dance. There is still abundance of native genius among them; but in the substantial parts of character they are a degraded nation. They perform the rights of hospitality with good humour and politeness, but will take the meanest shifts to gain some pecuniary remuneration, and will do any thing for the sake of money. Though avaricious, they are not sordid, but fond of pomp and show, and profuse in their ostentation of generosity. Wealth is the only object of their admiration; whence they are almost universally engaged in trade in some form or other. The cultivation of the soil is left to Albanians or colonists; and every Greek has a retail shop, or is concerned in some wholesale dealings. Even their princes and nobles who reside at Constantinople, are engaged in merchandize. They are little to be trusted; but are light, inconstant, treacherous, selfish, and subtle, in all their transactions, always awake to every opportunity of gaining an advantage; ready to practise the meanest artifices, and to utter the grossest untruths; regardless of character, and more barefaced in their impositions than even the Jews. They show a desperate frenzy in distress, and a bloody ferocity in power, but rarely display the coolness of determined courage, and seem scarcely capable of any prolonged struggle to regain their national freedom. See Chateaubriand's *Travels;* Clarke's *Travels;* Dallaway's *Tour in the Levant;* Savary's *Letters on Greece;* Hobhouse's *Tour in Albania*, &c.; Jackson's *Reflections on the Commerce of the Mediterranean;* and the works mentioned in the historical sketch of the Morea in this article. MORISON, Robert. See Botany.

MORLACHIA. See Dalmatia.

MOROCCO, or Marocco, frequently called West Barbary, is bounded on the north by the Mediterranean Sea; on the west by the Atlantic Ocean; on the south by the Sahara, or the great desert; and on the east by Tremecen, Sigelmessa, and Biledulgerid, or (according to modern and more correct orthography) Tlemsen, Segin Messa, and Bled-el-jerrede. The whole extent of this empire, including Tafilelt, is contained between 27° 40′ and 35° 40′ of N. Lat. and between 2° and 10° of W. Long. from London. It is divided into four great divisions: 1. The northern, containing the provinces of Erreef, El Garb, Benihassen, Temsena, Shawia, Tedla, and the district of Fez or Fas; 2. The central, containing the provinces of Duquella, Abda, Shedma, Haha, and the district of Morocco; 3. The southern, containing the provinces of Draha and Suse; and 4. The eastern, lying to the east of the Atlas Mountains, called Tafilelt, was formerly a separate kingdom, but became subjected to the princes of Morocco.

The principal mountains of Morocco are the Atlas Mountains, called in Arabic, Jibbel Attils, "The Mountains of Snow," the different branches of which have distinct names, according to the provinces in which they are situated. The great chain of these mountains runs through the whole extent of the empire, from Ape's Hill to Shtuka in lower Suse, passing within thirty miles of the city of Morocco, where they are of great height, and covered with snow throughout the whole year. They are visible at sea several leagues from the coast; and in a clear day may be seen at Mogadore, a distance of 140 miles. The highest peak is 12,000 feet above the level of the sea.

The rivers which rise to the east of the Atlas Mountains are the Draha, which flows through the province of the same name, from north-east to south, and disappears in the sands of the Sahara; and the Muluwra, which separates the empire of Morocco from Tremecen, flows to the northeast into the Mediterranean: both these rivers are deep and impetuous in the depth of winter, but small, and often quite dry, in summer. The other rivers, which all flow into the Atlantic Ocean, are the El kose, or Luccos, at El Araiche, which may be entered at high water by ships of 100 or 150 tons; the Baht, which partly loses itself in the lakes of the province El Garb, and partly falls into the Seboo; the Seboo, the largest river in the empire, rises to the east of the city of Fez, and falls into the sea at Meheduma or Mamora, where it is a large, deep, and navigable river; the Bu Regreg, which traverses the province of Benihassen, and discharges itself into the ocean between the towns of Salee and Rabat; the Morbeya, which rises in the Atlas Mountains, and falls into the Atlantic at the port of Azamor; the Tensift, which passes about five miles north of the city of Morocco, and reaches the ocean sixteen miles south of the town of Saffy, is chiefly remarkable for the salubrious quality of its water; the Tidsi, which falls into the sea a little south of Cape Ossem; the Suse, a fine majestic river, which joins the ocean six miles south of Santa Cruz, where its mouth is almost shut by a bar of sand, but which is supposed to have been once navigable as far as the town of Terodant; the Messa and Akassa, both of them partly navigable.

The western coast of Morocco is covered with numerous rocks, level with the surface of the water; and occasionally an extensive beach in the intermediate spaces, where the water is shallow, and the surf runs high.

There are several fresh-water lakes, particularly on the coast near the Mamora, one of which is 20 miles in length. These lakes abound with water-fowl and eels. The eels are taken and salted for sale; and, as the water is not deep, they are killed by a lance, while the fisherman sails along the surface in a slender skiff, made of the fan-palm and of rushes.

The climate of Morocco is healthy and bracing. From March to September the atmosphere is almost entirely free from clouds; and even in the rainy season from September to March, there is scarcely a day altogether without sunshine. In the province of Suse the climate is peculiarly delightful, but extremely hot in the months of June, July, and August, particularly when the Shume or hot wind blows from the desert. In the more inland districts of Draha and Tafilelt, this wind occasions intense heat in the months of July, August, and September.

The whole division north of the Morbeya is a fine champaign country, with a rich black and sometimes red soil, without stone or clay, with few trees, but remarkably productive in grain. The central provinces are equally fertile, and more abundant in pasturage.

The province of Haha, which is of great extent, is more mountainous; and that of Suse, still more extensive, is more particularly productive of the finest fruits. The more inland districts of Draha and Tafilelt are particularly fruitful in dates.

No roads are made in the country, and there are very few bridges. Except at the sea-ports, where boats are used, there is no way of passing the rivers, which are too deep to be forded, except by swimming, or on rafts. Hence, in the wet season, when the rivers are much swelled, travellers are frequently detained several days upon their banks.

Gold and silver mines are found in various parts of Morocco, particularly about Messa, in the province of Suse, and in the plains of Msegina, near Santa Cruz, which had formerly been worked by the Portuguese, but are now neglected. Gold is found also in the Atlas mountains, mixed with antimony and lead-ore; and iron, copper, and lead-ore, in Suse. At Tesellerst, near the southern frontier, the copper mines are very abundant; and in Tafilelt, the mines of antimony are of the finest quality. Immense quantities of sulphur are dug from the foot of the Atlas mountains opposite to Terodant. The salt-petre found at the same place is the purest and strongest; but it is also procured at Fez and Morocco. Mineral salt of a red colour is dug from quarries in various parts of the country; and in the province of Abda, there is an extensive lake, which furnishes a kind of salt superior to the mineral; but the purest of all is found among the rocks on many parts of the coast, where the summer sun has exhaled the salt-water in the cavities.

The principal vegetable productions of Morocco are the palm or date tree, of 30 different kinds, which is found in perfection in the southern parts of Suse, and particularly in Tafilelt; oaks, and a few other valuable trees, in the northern districts; cork trees, some of which are as large as full-grown oaks; olive-trees, which are of great size and beauty, in the southern districts, where the plantations are very extensive and productive. Various trees which yield the different kinds of gum, viz. Arabic, sandrac, ammoniac, Senegal, and euphorbium; wild juniper, which abounds in the Atlas mountains, and from which by burning a kind of pitch is extracted; various shrubs used in the preparation of leather; fig-trees which abound in every part of the empire, and produce the finest fruit; the Indian fig, or prickly pear, which grows to the height of twenty feet in the driest situations, and affords a peculiarly cooling fruit; almond trees in great abundance, particularly in Suse; apples, pears, apricots, plums, pomegranates, lemons, limes, citrons, and the most delicious oranges in the world, in the more northern provinces; grapes, melons, strawberries, and water-melons (particularly in the province of Duquella) of a prodigious size; sugar-cane, which grows spontaneously in Suse, and stick liquorice in the greatest abundance in that province; mallows and truffles; cotton of a superior quality; hemp, chiefly cultivated for the sake of its seeds and flowers, which are smoked for the purpose of intoxication; tobacco, of which the best is that of Mequinez; honey, wax, &c. The principal kinds of grain cultivated in the country are wheat and barley, peas, beans, caravances, and Indian corn; and these crops are generally so abundant, that the produce of one province, if fully raised, would suffice for the consumption of the whole empire.

The most remarkable of the animal creation in the Empire of Morocco are the horses, which are renowned for fleetness and action, particularly those of Abda, which have a stronger sinew than those of Europe, and with a little management are extremely tractable; the Keirie, or camel of the desert, which can perform in one day an ordinary three days, or seven days, or even a nine days' journey, and one of which is worth 200 camels; the horse of the desert, which lives chiefly on camel's milk, and is principally used in hunting the ostrich; mules and asses, camels and horned cattle, in all quarters; sheep of various qualities, but those of the southern provinces are remarkable for the fine flavour of their mutton, owing to the aromatic herbs on which they feed, and those of Tedla are distinguished by the fineness of their wool, which is soft as silk; goats, which are very prolific, particularly in Tafilelt, where they have young twice in the year, and some of them six kids in nine months. The principal wild beasts are lions, panthers, rhinoceroses, wild boars, hyænas, jackals, foxes, apes, antelopes, hares, squirrels, cameleons. The birds are ostriches, pelicans, eagles, flamingoes, storks, herons, bustards, wild geese, wild ducks, plovers, pigeons, wood-pigeons, turtle-doves, ring-doves, partridges, nightingales, starlings, black-birds, larks, cuckoos, owls, &c. The reptiles are lizards and serpents of various kinds, of which the most remarkable are the Boah, from 20 to 80 feet in length, and the Buskah and Effah, which are full of deadly venom. The insects most worthy of notice, are the locust, the ammoniac fly, and large loud-toned crickets. Whales have been sometimes seen on the coast of Morocco; mullet, brim, anchovies, sardines, herrings, mackarel, rock-cod, skaite, plaice, soles, turbot, turtle, and most of the fish found in the Mediterranean, are taken on the western shores of the empire, besides a fish peculiar to the coast, called izgal, which, when dried in ovens, forms a considerable article in commerce with the interior districts of Africa. The principal fresh-water fish of the country is the shebbel, similar to the salmon, a rich and delicate fish, which is dried and baked in great quantities for the use of those countries where the inhabitants live much on dates. Land-tortoises are very abundant, and of a great size. For a fuller description of the animals of the country, see Barbary.

The principal towns of Morocco are, Morocco, Mequinez, Mogadore, and Fez, (for an account of which see the respective articles under those heads,) Terodant, the old metropolis of the kingdom of Suse, an ancient and extensive town, in which there is a magnificent palace, adorned with delightful gardens, but now decreasing in population, and noted only for the manufacture of leather, saddles, dyeing of cloths, and the production of a superior kind of saltpetre. Santa Cruz, or Agadeer, the most southerly sea-port of the empire, strongly fortified by its elevated situation and numerous batteries, possessing one of the best roads for shipping, and formerly the centre of a very extensive commerce, but dismantled in the year 1773, in consequence of an attempt on the part of its governor to resist the power of the emperor Seedy Mahomet; Saffy, an ancient town, between two hills, which expose it to the torrents of winter, and increase the heat of the summer, surrounded by thick and lofty walls, possessing a road for shipping, safe in summer, but in winter exposed to violent gales, and carrying on a considerable trade in corn; El-Waladia, a small square town, situated on an extensive plain, with a very spacious harbour, capable of containing 500 sail of the line, but having its entrance obstructed by rocks; Mazagan, remarkable for its salubrious air and excellent water, which is drawn by buckets from wells 100 feet deep, and possessing also a curious subterranean cistern, constructed by the Portuguese, for collecting the rain water for the supply of the garrison; Azamore, in the province of Duquella, remarkable for the immense number of storks by which it is occupied, and which are said to exceed the number of the inhabitants; Fedala, in a delightful fruitful district, and furnished with a safe road for shipping, at all seasons; Rabat, a walled town, with docks for ship-building, and a manufactory of cotton cloth, but chiefly remarkable for the ruins of a magnificent mosque, of which the roof was supported by 360 marble columns, and for a subterranean cistern, the tower of which, above 180 feet high, has so gradual an ascent to the top, made of a mixture of lime and sand, that a man on horseback may ride to the summit; Sallee, on the opposite side of the river to Rabat, which is also a walled town, defended by batteries, and formerly had a harbour capable of admitting large vessels, but is now greatly obstructed by the accumulation of sand at the entrance of the river; Mamora, or Maheduma, now a deserted place, partly on account of the swarms of annoying insects by which it is infested, and chiefly occupied by fishermen, who take incredible quantities of a species of salmon, called shebbel, for the supply of the interior; Larache, or El Araiche, in a rich and beautiful tract, where the gardens of the Hesperides are supposed to have been situated, and formerly a place of considerable commerce, but since 1780 almost totally evacuated, by the orders of the emperor; Tangier, or Tinjiah, which was given by the crown of Portugal, in 1662, as a marriage portion, with the Princess Catherine, to Charles II. of England, but abandoned by the English in 1684, after they had demolished the fortifications, a place which has few productions in its vicinity for the purposes of commerce, but is still a favourable station for Moorish pirates; Ceuta, or Cibta, supposed to be of Carthaginian origin, and formerly the metropolis of the countries held by the Goths in Hispania Transfretana, now possessed by the Spaniards, though often besieged by the Mahommedans; Tetuan, or Tetawan, situated in a country which produces the finest fruits, particularly oranges, and which carries on a considerable trade in provisions with Gibraltar, but in which no Europeans are allowed to settle since the year 1770, in consequence of a Moor having been shot by an Englishman; Velis, or Bedis, situated between two mountains, and surrounded with excellent timber; and Melilla, a place celebrated for the best wax and honey, and which has been in the possession of the Spaniards since the beginning of the 16th century.

The government of Morocco is the most unlimited despotism, both in theory and practice. There are really no other laws than the will of the emperor, whose mandates must be obeyed, even though they should deviate from the principles enjoined by the Koran. He administers justice in person, where he resides, and hears all complaints in the hall of audience, generally twice, and sometimes four times a week. Every individual, of whatever country, sex, or station, has free access to his presence, and full permission to state his cause. Every applicant brings a present suited to his condition; and the smallest matter, even a few eggs, will be accepted. Judgment between the parties is always prompt, and considered as generally correct, unless where wealth has interposed to bribe the judge. In other places, remote from the court, the vice-regent or hashaw administers justice in like manner, according to the laws of the Koran, or as his own caprice may direct. All subaltern magistrates proceed in the same despotic manner, often using the authority of the emperor to enforce their exactions; and all of them having no other object than to extort money from any individual who is known to possess property to a considerable amount. Emissaries and spies are continually at work to discover the persons who have any treasures in their possession, and to find out grounds of accusation against them. These very extortioners are in their turn exposed to the same treatment from the emperor, who sends some unexpected order, accusing them of crimes and misdemeanors, and demanding their accumulated wealth for the imperial treasury. In every province is a governor, named a bashaw, who is appointed and removed at the will of the emperor; in every douar, or Arab encampment, a similar officer of government, called a sheik; and in every town another, called alcaid; each possessing, in their respective districts, equally unlimited power with the sovereign, except that their decision may be carried by appeal before the emperor. Under the alcaid is an officer named el-haikum, or deputy governor, and another denominated cadi, who acts both as a priest and a civil judge, and in whose absence any of the talbs or common priests is authorized to discharge the office.

Trifling offences are usually punished by the bastinado, or beating the back and legs with leather straps, which is sometimes executed with great severity. In greater crimes, particularly theft, the hands are cut off, or a leg or hand. Persons capitally punished are sometimes shot, run through the body with swords, knocked down with clubs, or beheaded. A peculiar mode of punishing offenders is tossing, which is so managed that the sufferer falls immediately upon his head; and there are executioners so expert at this practice, that they can throw persons up, so as at pleasure to break the head, dislocate the neck, fracture a leg or arm, or let them fall without any material injury. But almost every mode of cruelty is occasionally practised in this miserable country. These punishments are usually superintended by the emperor in person, and used formerly to be frequently inflicted by his own hand, but now are generally executed by some of the negro soldiers.

The principal officers of the court are, the effendi, or friend, who is the prime minister and responsible person in the state; the secretary to the treasury, (united with the office of the effendi,) who disburses the payments of the emperor, has several under secretaries; the master of the horse, with 120 assistants; the grand-chamberlain, with 17 assistants; and grand-falconer, (a hereditary office) with 20 assistants; the keeper of the great seal; two grand-stewards; five inspectors-general of all the emperor's affairs, of whom the effendi is the chief; three masters of ceremonies for public audiences, with 40 assistants; an interpreter-general for European languages, who is usually a renegado; two grand-keepers of the jewels and plate; a grand-master of the baths; two grand-keepers of the arsenal; two keepers of the emperor's goods and warehouses; three inspectors of mosques, &c.; five keepers of the provisions; two keepers of the library; two astrologers; four masters of the carriages; twelve sons of renegadoes, who have not had beards, employed in drawing the small carriages; three principal assistants for prayers, with several deputies; three bearers of the umbrella, with their assistants; the bearer of the sabre; two bearers of the basin; two bearers of the lance; the bearer of the watch; five bearers of the emperor's firelocks, with their assistants; the bearer of the standard; a physician and surgeon, with many kinds of tradesmen. All these officers receive no salaries from the emperor, but depend entirely on the perquisites which are paid to them by those who transact any business with the court; and even what they receive in this way is often liable to be seized by the sovereign, unless he be gratified by occasional presents.

The Harem forms a part of the palace, and communicates with it by a private door, used only by the emperor. The apartments are also on the ground-floor, square, and very lofty; and four of them enclose a spacious square area, into which they open by means of large folding doors, which serve the purpose also of windows. These areas, or courts, are floored with blue and white chequered tiling, and have a fountain in the centre, supplied by pipes from a large reservoir on the outside of the palace. Twelve of these courts, communicating with each other by narrow passages, form the harem; and the women whom it contains have free access to every part of it. The apartments are adorned externally with beautifully carved wood-work; and are generally hung on the inside with red damask, of various colours, and furnished with beautiful carpets on the floors, and mattresses in different places, for the purposes of sitting and sleeping. At each end is placed, merely by way of ornament, an elegant European mahogany bedstead, hung with damask, and covered with mattresses of various coloured silks; and large looking-glasses, clocks, and watches in glass cases, are hung around the walls. The sultana is called the mistress of the harem, but without any control over the other females; and she has a whole square for her own use, while each of the rest has only one apartment. Each female has a separate daily allowance from the emperor, according to the rank which they hold in his estimation, out of which she is expected to furnish herself with whatever she requires. This allowance, at the time of Lempriere's visit to the emperor of Morocco, was little more than half a crown sterling to the favourite sultana, and less in proportion to the others; but the emperor makes them occasional presents of money, dress, and trinkets; and they receive considerable sums from those who solicit their influence in obtaining favours from the court. In this way ambassadors, consuls, merchants, native or foreign, are most assured of gaining their object with the sovereign, who rather encourages negotiations through this channel. These females are never permitted to go out of the harem, unless by an order from the emperor; and, except an occasional walk within the bounds of the palace, or a journey from one palace to another, they are constantly immured within their prison. Four of these women are considered as wives of the emperor, and the rest as concubines. Many of these are Moorish women, as the Moors consider it an honour to have their daughters in the harem; some of them European slaves; several are negresses, and the usual number of the whole is from 60 to 100, besides their slaves and domestics. Priestesses, who are so far learned as to read and write, are employed to teach the younger part of the harem to repeat their prayers, and to instruct the older females in the principles of their religion. The inhabitants of the harem are seldom observed at any other employment, except forming themselves into circles for conversation, or hearing stories, bathing, dressing themselves, and perhaps working a little at the needle. The sons of the emperor's wives are considered as princes, who have an equal claim to the empire; and they are generally appointed to the government of some of the provinces, as bashaws. But the daughters and the children of the concubines are generally sent at a proper age to the city of Tafilelt (the inhabitants of which are all sharifs, or supposed descendants of Mahommed) where they finish their education and intimacy with their kindred in the place. It is the peculiar privilege of the imperial family, that is, of the emperor himself, his sons, and brothers, to have the benefit of umbrellas; the shade of which, in a climate like that of Morocco, is one of the greatest luxuries.

The revenue of the emperor consists of a tenth upon every article of consumption, as allowed by the Koran; an annual tax upon the Jews; custom-house and excise duties; tributes exacted from his own subjects, foreign states, and European merchants, in the form of presents; which last articles form the chief source of his income. The duties and tributes are so frequently changed that it is impossible to estimate their annual amount with any degree of certainty.

The army used to consist principally of black troops, the descendants of negroes imported from Guinea, amounting altogether to above 40,000, and sometimes even 100,000 men; of whom two-thirds are cavalry; but every man is considered as a soldier, and obliged to act in that capacity, whenever the emperor shall require his services. The present emperor, Muley Solyman, has diminished the proportion of black troops; but negroes are still employed as governors of cities, commanders of the body guard, eunuchs in the harem, and in other offices of state. About 6,000 of the standing army, form the emperor's body guard; and the rest are quartered in the different towns of the empire, under the bashaws of the provinces. The soldiery are clothed by the emperor, and receive a little pay, but depend chiefly upon plunder. They are distinguished from the other Moors only by their accoutrements, which consist of a long musket, a sabre, a small red leather box to hold their balls, and a powder horn slung over their shoulders. The army is under the direction of a commander-in-chief, some principal bashaws, and officers of divisions called Alcaides. They have little order and regularity in their manœuvres, and are more like a rabble than an army.

The Navy consists of about 20 small frigates, a few xebecks, and 30 row galleys. The number of seamen in the service is computed at 6,000; the whole commanded by one admiral; but, being chiefly used in piracy, they are seldom united as a fleet. The naval power of the empire is altogether contemptible; and the whole maritime department becoming every year less effective, from the filling up of the harbours by sand, and other causes of their demolition.

The sea-port towns of Morocco carry on a very limited commerce with foreign nations. European factories have been established in some of them at different times; but have been often abandoned altogether, on account of the continually varying orders of the emperors, relating to trade and other matters; and partly on account of the unwillingness of Europeans to transmit merchandise to a country where there is so little security for property. The European merchant has so many difficulties in recovering debts due to him by the natives, that credit is in a great measure annihilated, and the trade of Morocco is, in a manner, transformed into barter. The principal commercial place in the empire, is the port of Mogadore; into which are imported cloths, linens, muslins, damasks, raw silk, copperas, tea, sugar, iron, and iron nails, hardware, pewter, spices, copper, thread, mirrors, earthen-ware, knives, brass pans, glass, Mexico dollars; and from which are exported almonds, gums, bees-wax, oil of olives, goat-skins, hides, wool, feathers, elephant's teeth, drugs, tallow, leather, raisins. At this place

The annual value of imports has been	151,450*l.*
The annual value of exports .	127,679*l.*

This trade is obviously of a valuable description to Europe, as it carries off manufactured goods of all kinds, and furnishes useful raw materials in return; and might be considerably augmented for the interest of Great Britain, by the establishment of well qualified persons as consuls, to establish friendly treaties, and to serve as the authorized channels of communication with the Moorish government.

There are large weekly markets held in the metropolis, where all articles of foreign and home manufacture are bought and sold. At these times, samples of the different kinds of merchandize are carried up and down the streets by itinerant auctioneers, who proclaim the price offered, and who apprize the highest bidder of his purchase; to whom the article is delivered upon his paying the money, and the transaction terminates. A considerable trade is carried on between the principal cities of Morocco and Timbuctoo, by means of large caravans, which cross the great desert; and which usually complete their journey from Fez to Timbuctoo in the space of 129 days. The principal articles which they carry out, are German and Irish linens, muslins, cambrics, fine cloths, raw-silks, beads, brass nails, tea, sugar, spices, tobacco, salt, red woollen caps, sashes, shawls, and haiks of silk and gold, manufactured in Fez and Tafilelt They bring back gold in dust, rings and bars, elephant's teeth, gums of various kinds, and slaves; besides ostrich feathers, and ambergris collected on the confines of the desert.

The religion of the empire of Morocco is Mahommedism; but toleration is granted in some measure to any sect which does not admit a plurality of gods; and, on proper application, they are permitted to appropriate a place for public worship. There are Catholic establishments in Morocco, Mequinez, Mogadore, and Tangier. Through all the country, there are buildings of an octagonal form, called Zawiat, or Sanctuaries, with an uninclosed piece of ground attached to each, for the interment of the dead. In these places is a priest or saint, who superintends divine service, and the burial of the dead, and who is often applied to as arbiter in disputes. In these consecrated places, the wealthy inhabitants often deposit their treasures for security; and criminals find protection against the hand of justice. The other religious institutions of the empire, are so similar to those of other Mahommedan countries, as to render a separate account of them altogether superfluous.

The estimates given by different travellers of the population of the empire, are so irreconcileable with one another, that it is impossible to speak on the subject with any degree of certainty. The whole inhabitants of Morocco have been calculated at two, at six, and at fifteen millions. The last is the statement of Mr. Jackson, who made his extracts from the imperial register. The city of Morocco contains, or did recently contain,

According to Jardine . . .	20,000

The population of the empire of Morocco, is principally composed of two great original classes, the Berebbers, and the Arabs.

The Berebbers are the descendants of the original inhabitants of the country before the Arabian conquest; and occupy all the mountainous districts. Though they have acknowledged the authority of the Koran, they have tenaciously maintained their independence, and carry on a desultory warfare against their Mahommedan invaders. They are an athletic, hardy, and enterprising race, with regular, and sometimes handsome features, but remarkable for the ferocious expression of their eye. They are characterised by a peculiar scantiness of beard; and, in the southern districts, many of them have only a few straggling hairs on the upper lip, with a small tuft on the chin. Their whole dress consists of a woollen jacket without sleeves, and a pair of trowsers. They dwell in caves, mud huts, or hovels of stone and timber, which are generally situated on some commanding eminence, and frequently surrounded with walls furnished with loop-holes for musquetry. They cultivate the ground, and feed cattle; but are almost universally robbers; and fall without mercy upon all travellers, who have not purchased a protection from some of their chiefs. They are divided into a number of petty tribes, distinguished by the names of their respective patriarchs and founders, and speak a variety of dialects, quite distinct from the Roman and Arabic languages. The great subdivisions of this class of natives are the Errifi, who inhabit the extensive mountainous province of that name, on the shores of the Mediterranean, and who are the most athletic, ferocious and faithless of them all; the Berebbers of the interior, who occupy the highlands from the southern confines of Errif, to the vicinity of Fez and Mequinez, and who are similar to the former in person, but less savage in their disposition; the Berebbers of Middle Atlas, who resemble the last mentioned in most respects; and the Berebbers of south Barbary, who extend from Mogadore southwards, and from the eastern limits of Atlas to the sea coast—who are also called Shilluks. These last, who are sometimes described as a distinct race, are more diminutive in person than those of the north, and have, in general, also an effeminate tone of voice. They have more of the social qualities; and are more faithful in observing the promises of protection granted by their chiefs.

The Arabs, who are the direct descendants of the invaders of the country, compose the most numerous class of the population, and are scattered over the whole level districts of northern Africa, even to the confines of the Great Desert. They are generally tall and robust, with fine features, and countenances full of intelligence, their eyes large, black and piercing, their noses gently arched, their teeth white and regular, their beards full and bushy, their hair strong, straight, and universally black, their skin, in the northern parts, of a bright, clear, brown colour, gradually darkening to black, as they approach towards the south. They are all cultivators of the earth, and breeders of cattle, depending entirely on agricultural pursuits for subsistence. They dislike the restraints of cities, and dwell invariably in tents, in families that vary in number from ten to a hundred. Each of their tribes has its own chief or sheik, who explains the Koran, and administers justice; and in the centre of each encampment is a tent, appropriated for religious worship and the reception of travellers. They move from place to place as the pasturage fails, or the land becomes exhausted; and separate into different parties, as their number and flocks may require. On their march, the women are placed on the backs of the camels, the children and lambs in the panniers on each side; and the fowls instinctively perch upon the baggage. Part of the men on horseback are armed with muskets, and act as a guard to the party, while the rest drive along the herds. They are more violent, but less treacherous than the other classes; faithful to the laws of hospitality within the limits of their encampment, but ready to murder the last night's guest when they meet him again beyond these boundaries. They are perpetually engaged in war with one another, with the Berebbers, or with the troops of the sovereign, who are sent out to collect the taxes, and they carry on their hostilities with the most savage brutality; sometimes ripping up the dead bodies of their victims, to discover the riches which they suspect them to have swallowed for the purpose of concealment.

The Moors, a name used only by Europeans, are the inhabitants of the towns, whom the Arabs call Medainien, or towns people, and who call themselves Mooslim, or believers. They are a mixture of all the nations who have at any time settled in Northern Africa, and are subdivided into four classes: 1. Those descended from Arab families, who form the larger part of the population in the southern towns, and of those which border on Arab districts; 2. Those who are sprung from the Berebbers, who are more or less numerous in the towns, according to the proximity of the Berebber districts; 3. The Bukharie or black tribe, who are the descendants of the negroes who have been brought as soldiers into the country, and who are most numerous in Mequinez; and, 4. the Andalusie, the reputed descendants of the Arab conquerors of Spain, who form a large class in the towns of the north of Barbary, and are seldom seen to the south of the river Asa Moor. The two former classes distinguish themselves by the name of the tribes from which they have sprung, and keep up a close alliance with their kindred families in the country; but the two latter denominations are entire in themselves, as two distinct communities. The Moors are an indolent and taciturn race, jealous, deceitful, and cruel, losing even the natural affections in their extreme selfishness, and altogether degraded by the influence of their absurd religion, their gross ignorance, and their wretched government. The reader is referred to the Article Barbary for an account of the manners and customs of the inhabitants. See Chenier's *Present State of Morocco.* Lempriere's *Tour to Morocco;* Jackson's *Account of the Empire of Morocco; Narrative of* Adams, *a Sailor, with appendix* by Mr. Dupuis; Ali Bey's *Travels;* Keatinge's *Travels in Europe and Africa.* (*q.*)

MOROCCO, a city of West Barbary, and the metropolis of the empire of Morocco, is situated in the midst of a beautiful valley, formed by a chain of mountains on the north, and those of the Atlas on the south and east The country which immediately surrounds it is a fertile plain, diversified by clumps of shrubs and palm trees, and watered by numerous streams which descend from the Atlas mountains. About five miles from the city towards the south, are seen the emperor's gardens, and large inclosed olive plantations, which greatly increase the beauty of the surrounding scenery. The city was founded in A. D. 1052, by an Arab chief named Jusuf Teshfin, and is said to have encreased so rapidly, that, in the time of his grandson, it contained a million of inhabitants. Leo Africanus speaks of it as one of the largest cities in the world; but the extent of ground which it covered, (which is ascertained by the ancient walls which still exist, and which are only 7 or 8 miles in circuit,) contradicts the probability of its having ever contained so great a population. At present its inhabitants do not exceed 30,000; and many of its most magnificent buildings are in a state of ruin and decay. The walls are extremely thick, and are built of a cement of lime and sandy earth, called by the Moors tabbia, which is put into cases, and beaten together with square rammers. These walls are flanked by square towers, and surrounded by a wide and deep ditch. There are numerous entrances, consisting of large double portions, built of tabbia in the gothic style, the gates of which are regularly shut every night at certain hours. The streets are very narrow, dirty, and irregular; and the best houses are built in the midst of the gardens behind high walls of the rudest construction, as every proprietor is anxious to conceal his wealth from the eye of the public. Most of them, also, are constructed like forts for defence, and approached by a narrow lane, capable of admitting only a single horseman at a time. There are many temples or mosques in the city, but few of them remarkable for magnificence. One of them, which has a cistern under it for collecting water in the rainy season, has its central space supported by pillars of marble, and has a lofty square tower, with a winding terrace reaching to the top, from which Cape Cantin, distant about 120 miles, is distinctly visible. Another tower is remarkable from the circumstance of its having three golden balls on its top, weighing together, it is said, 10 quintals, or 1205 lbs. avoirdupois, which several kings, when in want of money, have in vain attempted to take down. The imperial palace, which faces mount Atlas, is built of hewn stone, ornamented with marble. The architecture of the principal gates is Gothic, embellished with various ornaments in the Arabesque style. The walls of some of the rooms are of fillagree work, and others of glazed tiles, which are fixed in the walls with much art, and which have a cooling effect. There are three gardens attached to the palace, abounding in the richest fruits and most fragrant flowers. In these gardens are irregular square buildings called pavillions, with pyramidal roofs, covered with glazed tiles of various colours, lighted by four lofty doors, and painted and gilt in the Arabesque style. In these pavillions the emperor takes coffee or tea, and transacts business with the officers of his court. They seldom contain any other furniture than a couple of sofas, some china and tea equipage, a clock, a water-pot, a few arms hung round the walls, and carpets to kneel upon in prayers. Near the palace is the place of audience, an extensive quadrangle, walled round, but open above, in which the emperor gives audience to his subjects, and administers justice. The Kasseria, a place of trade, is an oblong building, surrounded with small shops, filled with silks, cloths, and other valuable articles. These shops, like those of other towns in Morocco, are nothing more than openings in the walls about a yard from the ground. and just of sufficient height to admit a man to sit within them cross-legged, with the goods and drawers so arranged round him, that he can serve his customers, who stand in the street, without needing to move from his seat. At the extremity of the city, towards the Atlas mountains and near to the imperial palace, is the district occupied by the Jews, which forms a separate town of itself, with an alcaide appointed by the the emperor, to give them protection, and the gates of which are shut and opened at certain hours; but not much above 2000 Jews now reside in the place, as most of them prefer a dwelling in the adjacent mountains, where they are free from oppression and insult. In this quarter stands the Spanish convent, which used to be occupied by a few friars. but is now deserted. There is an ancient subterraneous aqueduct built of brick, twenty feet below the surface, which goes round the town, and from which pipes of brick work branch off at every hundred yards, to convey the water into the houses. But this aqueduct is much neglected, and the city is supplied with water by wooden pipes from numerous wells in the adjoining olive plantations. The wealthier inhabitants procure water from the river Tensift, which flows at a short distance from the city, and the water of which is accounted very salubrious, and particularly medicinal in cases of indigestion. Many of the streets are filled with the ruins of old houses, and in the Jew's quarter, the heaps of dung are as high as the houses. The houses are also greatly infested with vermin, particularly with bugs, which, in the summer season, literally cover the walls. The air around the city is generally calm, and the climate healthy, as the neighbouring mountains of Atlas, which are always covered with snow, serve at once to cool the surrounding atmosphere, and to furnish a shelter from the scorching winds of the desert. W. Long. 7°. North Lat. 30° 57′. (*q*.)

MORPETH, is the name of a market and borough town of England, in the county of Northumberland. The town is situated among woody undulating hills, on the great north road from Edinburgh to London, on the banks of the river Wensbeck, which is crossed by a stone-bridge. It consists principally of one long street, which is spacious, and contains many well-built and neat houses. The principal buildings are the parish church, which is built on Kirk Hill, a quarter of a mile from the town; a handsome town-house, built by the Earl of Carlisle in 1714, from a design of Vanburgh; the county gaol, which stands near the bridge, and is well built and well managed. The charitable establishments are a free school, founded by Edward VI. and an hospital for old persons. The principal piece of antiquity here is the castle, which stands on an eminence above the town. A part of the gateway, tower, and fragments of the outward wall, only remain. On the north side of the castle is a round mound of earth, which was probably a malvoisin in some blockade. A fragment of the door-way of the New Minster Abbey of White Monks still remains. Morpeth sends two members to parliament, and the right of election is vested in about 200 burgesses. The population of Morpeth, in 1811, was

MORRIS (Robert). The life of an individual who, for a long period, held a prominent station in society, and rendered important services to this country, deserves particular notice in a work of this nature. The writer regrets that the short time allowed him to furnish it, will render the account brief.

Robert Morris was the son of a respectable merchant of Liverpool, England, who had for some years been extensively concerned in the American trade; and while a boy, was brought by his father to this country, in which it appears he intended to settle. During the time that the subject of this sketch was pursuing his education in Philadelphia, he unfortunately lost his father, in consequence of a wound received from the wad of a gun, which was discharged as a compliment by the captain of a ship consigned to him, that had just arrived at Oxford, the place of his residence, on the eastern shore of the Chesapeake Bay; and was thus left an orphan at the age of fifteen years. In conformity to the intentions of his parent, he was bred to commerce, and served a regular apprenticeship in the counting-house of the late Mr. Charles Willing, at that time one of the first merchants of Philadelphia. A year or two after the expiration of the term for which he had engaged himself, he entered into partnership with Mr. Thomas Willing. This connection, which was formed in 1754, continued for the long period of thirty-nine years, not having been dissolved until 1793. Previously to the commencement of the American war, it was, without doubt, more extensively engaged in commerce, than any other house in Philadelphia.

Of the events of his youth we know little. The fact just mentioned proves, that although early deprived of the benefit of parental counsel, he acted with fidelity, and gained the good will of a discerning master. The following anecdote will show his early activity in business, and anxiety to promote the interests of his friend. During the absence of Mr. Willing at his country place near Frankford, a vessel arrived at Philadelphia, either consigned to him, or that brought letters, giving intelligence of the sudden rise in the price of flour at the port she left. Mr. Morris instantly engaged all that he could contract for, on account of Mr. Willing, who, on his return to the city next day, had to defend his young friend from the complaints of some merchants, that he had raised the price of flour. An appeal, however, from Mr. Willing to their own probable line of conduct, in case of their having first received the news, silenced their complaints.

Few men in the American colonies were more alive to the gradual encroachment of the British government upon the liberties of the people, and none more ready to remonstrate against them, than Mr. Morris. His signature on the part of his mercantile-house firm to the non-importation agreement, as repected England, which was entered into by the merchants of Philadelphia in the year 1765, while it evinced the consistency of his principles and conduct, at the same time was expressive of a willingness to unite with them in showing their determination to prefer a sacrifice of private interest to the continuance of an intercourse, which would add to the revenue of the government that oppressed them. The extensive mercantile concerns with England of Mr. Morris's house, and the large importations of her manufactures and colonial produce by it, must have made this sacrifice considerable. His uniform conduct on the subject of the relative connexion between England and the Colonies, his high standing in society, and general intelligence, naturally pointed him out as a fit representative of Pennsylvania in the national councils, assembled on the approach of the political storm; and he was accordingly appointed by the legislature of Pennsylvania, in November 1775, one of the delegates to the second congress that met at Philadelphia. A few weeks after he had taken his seat, he was added to the secret committee of that body, which had been formed by a resolve of the preceding congress (1775,) and whose duty it was "to contract for the importation of arms, ammunition, sulphur, and saltpetre, and to export produce on the public account to pay for the same." He was also appointed a member of the committee for fitting out a naval armament, and specially commissioned to negotiate bills of exchange for congress; to borrow money for the marine committee, and to manage the fiscal concerns of congress upon other occasions. Independently of his enthusiastic zeal in the cause of his country, his capacity for business, and knowledge of the subjects committed to him, or his talents for managing pecuniary concerns, he was particularly fitted for such services; as the commercial credit he had established among his fellow citizens probably stood higher than that of any other man in the community, and this he did not hesitate to avail himself of, whenever the public necessities required such an evidence of his patriotism. These occasions were neither few nor trifling. One of the few remaining prominent men of the revolution, and who filled an important and most confidential station in the department of war, bears testimony that Mr. Morris frequently obtained pecuniary and other supplies, which were most pressingly required for the service, on his own responsibility, and apparently upon his own account, when, from the known state of the public treasury, they could not have been procured for the government. Among other facts in point may be mentioned, the prompt and fortunate supply of cash which he was enabled to furnish the commander in chief, while he lay on the Delaware with the army, opposite to Trenton, (December, 1776,) and which he had written for, as essentially necessary to enable him to obtain such intelligence of the movement and position of the enemy, as would authorize him to act offensively. The requisite sum was obtained from a member of the society of Friends, upon the written obligation of Mr. Morris; and this timely compliance with the demand, enabled general Washington to make the attack, and gain the signal victory at Trenton over the savage Hessians; a victory which, exclusively of the benefits derived from its diminishing the numerical force of the enemy by nearly one thousand, was signally important in its influence, by encouraging the patriots, by checking the hopes of the enemies of our cause, and by destroying the impression which the reputed prowess of the conquered foe, and the experience of their ferocity over the unprotected and defenceless, had made upon the people. Upon another occasion, he became responsible for a quantity of lead, which had been most urgently required for the army, and which most providentially arrived at the time when greatly wanted. At a more advanced stage of the war, when pressing distress in the army had driven congress and the commander in chief almost to desperation, and a part of the troops to mutiny, he supplied the army with four or five thousand barrels of flour, upon his own private credit; and, on a promise to that effect, persuaded a member to withdraw an intended motion to sanction a procedure which, although common in Europe, would have had a very injurious effect upon the cause of the country: this was no less than to authorize general Washington to seize all the provision that could be found within a circle of twenty miles of his camp.* While financier, his notes constituted, for large transactions, part of the circulating medium. Many other similar instances occurred of this patriotic interposition of his own personal responsibility for supplies, which could not otherwise have been obtained.

In the first year in which he served as a representative in congress, he signed the memorable parchment containing the declaration that for ever separated us from England, and thus pledged himself to join heart and hand with the destinies of his country, while some of his colleagues, who possessed less firmness, drew back and retired from the contest. He was thrice successively elected to congress, in 1776, '77, and '78.

The exertion of his talents in the public councils, the use of his credit in procuring supplies at home, of his personal labour as special agent, or congressional committee-man, and of those in his pay, in procuring others from abroad, were not the only means employed by him in aiding the cause in which he had embarked. The free and public expression of his sentiments upon all occasions, in the almost daily and nightly meetings of the zealous; in the interchange of friendly intercourse with his fellow citizens, and the confident tone of ultimate success which he supported, served to rouse the desponding, to fix the wavering, and confirm the brave. Besides, the extensive commercial and private correspondence which he maintained with England, furnished him with early intelligence of all the public measures resolved on by the British government, the debates in parliament, and with much private information of importance to this country. These letters he read to a few select mercantile friends, who regularly met in the insurance room at the Merchants' Coffee-house, and through them the intelligence they contained was diffused among the citizens, and thus kept alive the spirit of opposition, made them acquainted with the gradual progress of hostile movements, and convinced them how little was to be expected from the government in respect to the alleviation of the oppression and hardships against which the colonies had for a long time most humbly, earnestly, and eloquently remonstrated. This practice, which began previously to the suspension of the intercourse between the two countries, he continued during the war: and through the route of the continent, especially France and Holland, he received for a time the despatches which had formerly come direct from England.

The increasing and clamorous wants of the army, particularly for provisions, and the alarming letter written by the commander in chief to congress on the subject, on being communicated to Mr. Morris, induced him to propose to raise an immediate fund to purchase supplies, by

* Debates on the renewal of the charter of the Bank of North America, p. 47. Philadelphia, 1786.

the formation of a paper-money bank; and to establish confidence in it with the public, he also proposed a subscription among the citizens in the form of bonds, obliging them to pay, if it should become necessary, in gold and silver, the amounts annexed to their names, to fulfil the engagements of the bank. Mr. Morris headed the list with a subscription of 10,000*l.*; others followed, to the amount of 300,000*l.* The directors were authorized to borrow money on the credit of the bank, and to grant special notes, bearing interest at six per cent. The credit thus given to the bank effected the object intended, and the institution was continued until the Bank of North America went into operation, in the succeeding year.* It was probably on this occasion, that he purchased the four or five thousand barrels of flour above mentioned, on his own credit, for the army, before the funds could be collected to pay for it.†

If the grand, and as regarded the fate of the union, the decisive measure of the attack on Cornwallis, did not originate with Mr. Morris, as the facts communicated to the writer induce him to believe; there can be no doubt of his warmly approving it, that he first proposed it to the commander in chief, and provided the funds to enable general Washington to move the army. At that time, the American army lay at New-Windsor, waiting for the French fleet and troops from the West Indies, to co operate with them in an intended attack on New-York; but count De Grasse, the French admiral, changed the destination of his squadron, and went into the Chesapeake. The serious nature of the proposed operation in the south, and his total inability, from the want of funds, to move the army, induced general Washington to hesitate in giving his assent to the proposition; but the promise of Mr. Morris to supply the necessary means, overcame his scruples, and the first intelligence congress had of the movement, was the march of the troops, on the third of September, through Philadelphia. It was not, however, until the army had passed the city 15 miles, that he was relieved from his anxiety respecting his promise to general Washington of a competent pecuniary supply. His object, for this end, was the loan of the French military chest, and the proposition was made to the French minister Luzerne, who refused in the most positive manner to assent. His persuasive talents succeeded with count Rochambeau, and at Chester, whither Mr. Morris repaired, it was obtained. It is probable that the joy naturally felt on meeting at that place an express from the marquis Fayette, announcing the arrival of count De Grasse in the Chesapeake, with an assurance from Mr. Morris that our army could not move without funds, contributed to the obtaining this fortunate loan.

In the year 1781, Mr. Morris was appointed by congress "superintendant of finance," an office then for the first time established. This appointment was unanimous. Indeed, it is highly probable, that no other man in the country would have been competent to the task of managing such great concerns as it involved, or possessed, like himself, the happy expedient of raising supplies, or deservedly enjoyed more, if equal public confidence among his fellow citizens, for punctuality in the fulfilment of his engagements. As the establishment of the office of finance, and the appointment of Mr. Morris to fill it, formed an epoch in the history of the United States, and in the life of that officer, it merits particular notice.

It is well known that the want of a sufficient quantity of the precious metals in the country, for a circulating medium, and the absolute necessity of some substitute to carry on the war, induced congress, from time to time, to issue paper bills of credit to an immense amount. For a time, the enthusiastic zeal and public spirit of the people induced them to receive these bills as equal to gold and silver; but, as they were not convertible into solid cash at will, and no fund was provided for their redemption, depreciation naturally followed, as a necessary result, and with it public credit. "In the beginning of the year 1781, the treasury was more than two millions and a half in arrears, and the greater part of the debt was of such a nature, that the payment could not be avoided, nor even delayed: and therefore Dr. Franklin, then our minister in France, was under the necessity of ordering back from Amsterdam monies which had been sent thither for the purpose of being shipped to America. If he had not taken this step, the bills of exchange drawn by order of congress must have been protested," and a vital stab thereby given to the credit of the government in Europe. At home, the greatest public as well as private distress existed; "public credit had gone to wreck, and the enemy built their most sanguine hopes of overcoming us upon this circumstance:"‡ and "the treasury was so much in arrears to the servants in the public offices, that many of them could not, without payment, perform their duties, but must have gone to gaol for debts they had contracted to enable them to live." To so low an ebb was the public treasury reduced, that some of the members of the board of war declared to Mr. Morris, they had not the means of sending an express to the army.§ The pressing distress for provision among the troops at the time, has already been mentioned. The paper bills of credit were sunk so low in value, as to require a burthensome mass of them to pay for an article of clothing. But the face of things was soon changed. One of the first good effects perceived, was the *appreciation*‖ of the paper money; "this was raised from the low state of six for one, to that of two for one, and it would have been brought nearly, if not entirely to par, had not some measures intervened, which, though well meant, were not judicious." The plan he adopted was, "to make all his negotiations by selling bills of exchange for paper money, and afterwards paying it at a smaller rate of depreciation than that by which it was received; and at each successive operation the rate was lowered, by accepting it on the same terms for new bills of exchange, at which it had been previously paid. It was never applied to the purchase of specific supplies, because it had been checked in the progress towards par, and therefore, if it had been paid out in any quantity from the treasury, those who received it would have suffered by the consequent depreciation."

A minute's reflection will show the arduous nature of the duties he undertook to discharge.

In old organized governments, where a regular routine of a department has been long established, and the

* Of ninety-six subscribers who gave their bonds, six only are alive, viz. Charles Thompson, Richard Peters, Thomas Leiper, Wm. Hall, John Donaldson, and John Mease. For the original list, and account of the bank, see the Pennsylvania Packet for June, 1781.

† Debates on the Bank of North America, p. 47.

‖ This word appears to have been coined during the revolution, and used as the opposite of *depreciation.*

details, as it were, brought to perfection, by gradual improvement, derived from the experience and talents of successive officers, little difficulty is experienced by the new incumbent in continuing the customary train of operations. Simple honesty, attention to duty, and a careful progress in the path previously pointed out, are all the requisites; but the state of public affairs, and especially in the fiscal department of the United States at the time alluded to, furnished none of these helps. Every thing was in the greatest confusion; and a new system of accounts was not only required to be devised, but the means of supplying the numerous and pressing wants of the public service to be discovered, and those wants attended to. The task would have appalled any common man; but the natural talents of Mr. Morris, together with his experience and habits of despatch, derived from his extensive commercial concerns for a long series of years, and an uncommon readiness, great assiduity and method in business, with decision of character, enabled him to surmount all the difficulties that lay in his way. An inspection of the official statement of his accounts, will at once show the serious nature of the multifarious duties attached to the office, and the pressure of his engagements; but an opportunity of so doing, even if wished for, can be had by few. Some idea may be formed of them, when it is known, that he was required "to examine into the state of the public debts, expenditures, and revenue; to digest and report plans for improving and regulating the finances; and for establishing order and economy in the expenditure of public money." To him was likewise committed the disposition, management, and disbursement of all the loans received from the government of France, and various private persons in that country and Holland; the sums of money received from the different states; and of the public funds for every possible source of expense for the support of government, civil, military, and naval; the procuring supplies of every description for the army and navy; the entire management and direction of the public ships of war; the payment of all foreign debts; and the correspondence with our ministers at European courts, on subjects of finance. In short, the whole burthen of the money operations of government was laid upon him. No man ever had more numerous concerns committed to his charge, and few to a greater amount; and never did any one more faithfully discharge the various complicated trusts with greater despatch, economy, or credit, than the subject of this sketch. The details of his management of the office of finance, may be seen in the volume which he published in the year 1785.* It is well worth inspecting by every American. The preface,† in particular, should be read attentively, as he will from it form some idea of the state of public affairs, as to money, at the time; of the difficulties attending the revolutionary struggle on that account, and the means by which our independence was secured, or greatly promoted, and for the enjoyment of which he ought never to cease to be thankful.

The establishment of the Bank of North America forms a prominent item in the administration of Mr. Morris. The knowledge which he had acquired of the principles of banking, and of the advantages resulting to a commercial community from a well regulated bank of discount and deposit, in enabling merchants to anticipate their funds in cases of exigency, or of occasions offering well grounded schemes of speculation,‡ rendered a hint on the subject of the importance of a bank to the government, enough; and he accordingly adopted it with warmth. Such an institution had been previously suggested, and as already said, an attempt at one, although with paper-money, but backed by the bonds of responsible men, had been made the preceding year. The greater facilities which one with a specie capital promised, in enabling the government to anticipate its revenue, and to increase the quantity of circulating medium, and promote trade, were forcibly impressed on his mind, and induced him to propose it to Congress. In May, 1781, he presented his plan, which was approved of by that body. Subscriptions were opened shortly after; but, in the following November, when the directors were elected, "not two hundred out of a thousand had been subscribed, and it was some time after the business of the bank was fairly commenced," before the sum received upon all the subscriptions amounted to $70,000." Mr. Morris, no doubt, became sensible that such a capital would go but a little way in aiding him in his financial operations for government, and at the same time accommodate the trading part of the community. He therefore subscribed $250,000 of the $300,000, (which remained of the money received from France,) to the stock of the bank, on the public account: $450,000 had been brought from France, and lodged in the bank, and he "had determined, from the moment of its arrival, to subscribe, on behalf of the United States, for those shares that remained vacant; but such was the amount of the public expenditures, that notwithstanding the utmost care and caution to keep this money, nearly one half of the sum was exhausted before the institution could be organized."§ It was principally on this fund that the operations of the institution were commenced; and before the last day of March, the public obtained a loan of $300,000, being the total amount of their then capital. This loan was shortly after increased to $400,000.‖ Considerable facilities were also obtained by discounting the notes of individuals, and thereby anticipating the receipts of public money; besides which, the persons who had contracted for furnishing rations to the army, were also aided by discounts upon the public credit. And in addition to all this, the credit and confidence which were revived by means of this institution, formed the basis of the system through which the anti-

"*To the Inhabitants of the United States.*

"FELLOW-CITIZENS,

"That every servant should render an account of his stewardship, is the evident dictate of common sense. Where the trust is important, the necessity is increased; and where it is confidential, the duty is enhanced. The master should know what the servant has done. To the citizens of tbe United States, therefore, the following pages are most humbly submitted."

‡ Mr. Morris stated, in his speech on tbe renewal of the charter of the Bank of North America, that before the American war, he had "laid the foundation of a bsnk, and established a credit in Europe for the purpose. From the execution of the design, he was prevented only by the revolution." Debates, p. 37.

§ Debates on Bank, p. 48.

‖ The sum total brought into the public treasury, from the several states, not amounting to $30,000 upon tbe last day of June.

cipations made within the bounds of the United States had, in July, 1783, exceeded $820,000. If the sums due, (indirectly) for notes of individuals discounted, be taken into consideration, the total will exceed one million! It may then not only be asserted, but demonstrated, that without the establishment of the national bank, the business of the department of finance could not have been performed."

Besides this great benefit to the public cause, derived from the bank; the state of Pennsylvania, and city of Philadelphia, by loans obtained from it, were greatly accommodated. It enabled the first to provide for the protection of the frontiers, then sorely assailed, and to relieve the officers of the Pennsylvania line from their distress, occasioned by the failure of the internal revenue, which had been mortgaged for payment of interest of certificates granted them for military services. It enabled the merchants to clear the bay, and even river Delaware, of the hostile cruisers (which destroyed the little commerce that was left, and harassed our internal trade,) by fitting out, among other armed vessels, the ship "Hyder Ally," which, under the command of the late gallant Barney, in four days after she sailed, brought into port the sloop of war General Monk, which the British, with accurate knowledge of all public movements, had fitted out at New York, with the particular object of capturing her.* By its loans, the city authorities relieved the pressing wants of the capital, which suffered in a variety of ways from the exhausted state of its funds, the necessary consequence of the war. But the support of public credit, the defence of the state and harbour, and relief of the city funds, were not the only results from this happy financial expedient of Mr. Morris: for by its accommodations to the citizens, it promoted internal improvements, gave a spring to trade, and greatly increased the circulating medium by the circulation of its notes, which, being convertible at will into gold or silver, were universally received equal thereto, and commanded the most unbounded confidence. Hundreds availed themselves of the security afforded by the vaults of the bank to deposit their cash, which, from the impossibility of investing it, had long been hid from the light; and the constant current of deposits in the course of trade, authorized the directors to increase their business, and the amount of their issues, to a most unprecedented extent. The consequence of this was a speedy and most perceptible change in the state of affairs, both public and private.

In the same year, an additional mark of confidence reposed in the talents and integrity of Mr. Morris, was evinced by the legislature of Pennsylvania, by their appointment of him as their agent to purchase the supplies demanded of the state for the public service. By the nature of the organization of the general government, the annual necessities of the public funds, provisions and other supplies were apportioned among the several states, and large demands were made upon Pennsylvania in 1781. Mr. Morris was appointed to furnish them, and a particular resolve of Congress permitted him to undertake the trust. The supplies were furnished in anticipation, before the money was obtained from the state treasury, and while he thus enabled the state promptly to comply with the demands of Congress, he shows, by his account of the transaction, that the plan of his operations was more economical than any other, which, under the state of things at the time, could have been adopted. Those only who are old enough to recollect the state of parties at the time in Pennsylvania, or have made themselves acquainted with them, can duly appreciate the extent of the compliment paid to Mr. Morris by his appointment upon the occasion mentioned. Political feuds, arising in part from a difference of opinion on the subject of the constitution of Pennsylvania of 1776, prevailed to a great extent, and the conduct of the ruling party, who were opposed to any change in that feeble instrument, was, on many occasions, marked by want of both intelligence and liberality of sentiment. Mr. Morris was considered the head of what they chose to term the aristocratic party, that is, that portion of men of wealth, great public consideration, superior education, and liberal ideas, who ardently wished a more energetic form of state government than could exist under a single legislature, and numerous executive council; and could the legislature have dispensed with his services, or had there been any man among the party in power, capable of fulfilling the trust, it is probable that he would not have been appointed to it. That man, however, did not exist. The manner in which Mr. Morris executed it, showed how well he merited the confidence of the legislature, and also a skilfulness of management, which none but himself could have effected.†

In the year 1786, Mr. Morris served as a representative of Philadelphia, in the state legislature. Always ready to lend the aid, either of his talents, time, or purse, when required by the cause of his country, or state; he consented to the wishes of his fellow-citizens in standing as a candidate, for the express purpose of exerting his influence in favour of the renewal of the charter of the Bank of North America, which had been taken away from that institution by the preceding assembly. The ostensible reasons for this unjust measure were ill-grounded fears of the evil effects of the bank on society, (and especially the agricultural interest,) its incompatibility with the safety and welfare of the state; an improbable possibility of undue influence from it on the legislature itself; with other arguments of equal weight and truth. But the real cause must be ascribed to the con-

* The following statement of the comparative force of the two vessels, and merit of the capture of the Monk, was published in a newspaper of the day.

1. The General Monk carried 18 nine pounders; the Hyder Ally carried only 4 nines and 12 six pounders.
2. The General Monk carried 130 men: the Hyder Ally only 120 men.
3. The General Monk was completely fitted for sea, and was officered and manned with a crew regularly trained, and perfectly disciplined, by long experience, in the British navy. The Hyder Ally was a letter of marque a few days before the battle. Most of her officers were young men. Her captain brought up in a counting-house, and became a sea-officer, as many of our farmers, lawyers, and doctors became generals, from necessity and patriotism. The crew was picked up the week before in the streets of Philadelphia; many of them were landsmen, and most of them had never been in action before.
4. The General Monk lost 53 men in killed and wounded; the Hyder Ally lost only 11.

Add to these circumstances, that the victory, under all these disparities, was obtained in 25 minutes, and it will appear to be one of the most honourable exploits to the flag of the United States, that occurred during the war.

† See the Statement of his Finance Accounts, before referred to.

tinuance of the spirit of the same party which had been so violently opposed to Mr. Morris, and the society with which he associated during the whole of the American war. The debates on the occasion, which excited great interest among all classes of society, were accurately taken down, and published in a pamphlet.* Mr. Morris replied to all the arguments of his opponents with a force of reasoning that would have produced conviction in the minds of any men, not previously determined to destroy the bank, if possible, at all hazards. The question, however, was lost by a majority of 13, (28 to 41.) The succeeding legislature restored the charter.

The next public service rendered by Mr. Morris to his country, was as a member of the convention that formed the federal constitution in 1787. He had, as a part of his colleagues, Benjamin Franklin, George Clymer, and James Wilson, with whom he assisted in the councils that led to the memorable and decisive measures of the year 1776; and now with them again united in forming the bond of union, which was to lay the foundation for the future and permanent prosperity of their country. The want of an efficient federal government in conducting the war, had been severely felt by all those at the head of affairs, either in a civil or military capacity, and most particularly by Mr. Morris, while a member of Congress, and afterwards when the financial concerns of the Union were exclusively committed to him; and the necessity of it, "one, which would draw forth and direct the combined efforts of United America," was strongly urged by him, in the conclusion of his masterly preface to the "Statement of his Finance Accounts," already referred to.

The confidence of his fellow-citizens was again shown, in his election as one of the representatives from Philadelphia, in the first Congress that sat at New-York after the ratification of the federal compact by the number of states required thereby, to establish it as the grand basis of the law of the land.

It adds not a little to the merit of Mr. Morris to be able to say, that notwithstanding his numerous engagements as a public or private character, their magnitude, and often perplexing nature, he was enabled to fulfil all the private duties which his high standing in society necessarily imposed upon him. His house was the seat of elegant, but unostentatious hospitality, and his domestic affairs were managed with the same admirable order which had so long, so proverbially distinguished his counting-house, and the offices of the secret committee of Congress, and that of Finance. This happy union of well-conducted official and domestic concerns, was owing, in the first case, to his own superior talents for despatch, and method in business, and, in the last, to the qualifications of his excellent partner, the sister of the esteemed bishop of Pennsylvania, Dr. White. An introduction to Mr. Morris, was a matter of course, with all the strangers in good society, who for half a century visited Philadelphia, either on commercial, public, or private business, and it is not saying too much to assert, that during a certain period, it greatly depended upon him to do the honours of the city: and certainly no one was more qualified or more willing to support them. Although active in the acquisition of wealth as a merchant, no one more freely parted with his gains, for public or private purposes of a meritorious nature, whether these were to support the credit of the government, to promote objects of humanity, local improvement, the welfare of meritorious individuals in society, or a faithful commercial servant. The instances in which he shone on all these occasions were numerous. Some in reference to the three former particulars have been mentioned, and more of his disinterested generosity in respect to the last could be given, were the present communication intended to be any thing more than a hasty sketch. The prime of his life was engaged in discharging the most important civil trusts to his country, that could possibly fall to the lot of any man; and millions passed through his hands as a public officer, without the smallest breath of insinuation against his correctness, or of negligence, amidst the "defaulters of unaccounted thousands," or the losses sustained by the reprehensible carelessness of national agents.

From the foregoing short statement, we may have some idea of the nature and magnitude of the services rendered by Mr. Morris to the United States. It may be truly said, that few men acted a more conspicuous or useful part; and when we recollect that it was by his exertions and talents that the United States were so often relieved from their difficulties at times of great depression and pecuniary distress, an estimate may be formed of the weight of obligations due to him from the people of the present day. Justly, therefore, may an elegant historian of the American War say, "Certainly the Americans owed, *and still owe*, as much acknowledgment to the financial operations of Robert Morris, as to the negotiations of Benjamin Franklin, or even the arms of George Washington.†"

After the close of the American war, Mr. Morris was among the first in the States who extensively engaged in the East India and China trade. He died in Philadelphia, in the year 1806, in the 73d year of his age.

MEASE.

MORTALITY, BILLS OF. See ANNUITIES.

MORTAR. See ORDNANCE.

MOSAIC, commonly designed *Painting in Mosaic*, is a mode of representing objects by the union of portions of stone or glass, reduced to an even surface. But it is always a copy, for artists in Mosaic never compose.

The materials are few and simple, consisting merely of the substance with which the picture is to be represented, formed into cubes, parallelopipeds, or other polygonal figures, as required, and retained by one end in a strong cement, to preserve the union of the whole. Their colour, size, and substance, are arbitrary with the artist, according to the subjects and future position: all, however, are of the most durable kind. The ancient Mosaics consisted chiefly of marble and coloured glass or pastes; the modern are composed of marble, glass, enamel, and sometimes of the harder stones, as agate, cornelian, lapis lazuli, and even jewels. From the variety of design, and diversity of shades, the works of the latter evince great superiority over the former, for the ancients used few colours, and the same design was frequently repeated.

In general, Mosaics are composed of cubes, or short parallelopipeds, that is, oblong pieces of from two inches of a side, down to fragments of the smallest surface, as is seen in a portrait of Pope Paul V. where the face alone consists of 1,700,000 portions, each no larger than

* For this interesting document, we are indebted to Mr. Mathew Carey, as writer and publisher.

† Botta's Hist. Am. War, vol. iii. p. 343.

a grain of a millet. The Mosaic of the cupola of St. Peter's at Rome, on the other hand, is formed of unpolished coloured stones, of from half an inch to two inches square; and pavements appear in pieces still larger. Of this last description, or of what may be called large Mosaic, the pieces are reduced to the necessary size by sawing and grinding, after the ordinary operations of the lapidary; those of glass, which is in universal use, are broke down from rods, drawn out of a suitable shape; but glass being a refractory substance, enamel is substituted for it, as it is more easily managed in reduction. The enamel which is used for smaller pictures, is drawn out into long quadrangular rods while fused, and these are broke across with a hammer, or divided by a file into portions longer or shorter as required. It is so fusible, that the rods of inconsiderable size, may be drawn out by the flame of a candle, without assistance of the blow-pipe. In using the finer hard stones, they also are fashioned into the proper form, by the art of the lapidary; but the expense of purchase, and the labour of workmanship, restrict the fabrication of such Mosaics. Most of the enamel employed for this purpose was formerly prepared in Holland and at Venice, in small round cakes, four or five inches in diameter, and five, six, or eight lines thick, which were sent to the chief places of manufacture in Italy, as Milan, Rome, and Florence. Being dexterously struck with a hammer, on an anvil of a particular shape, fragments more regular than those of other substances fly off in the fracture, and commonly approaching an oblong form. At Rome, where it is now carried on extensively, all the materials are compounded.

Such artificial substances are prepared of a vast variety of different shades, in order to obtain the suitable gradation of colour in the picture. Hence the present number of tints in Mosaic is said to amount to no less than 15,000 or 17,000, proceeding by a nicety almost inconceivable. About 50 years ago they were computed at 4000: and it seems evident that the increase has been great and gradual, and most probably an object of more attention in later times; for ancient Mosaics, on which considerable labour has been bestowed, appear in only three colours.

The numerous fragments from each species of substance are all arranged in drawers, boxes, and cases regularly labelled, from which they are withdrawn by the artist for his work, as the compositor selects types for printing. It is necessary to explain, that, in composing a large picture in Mosaic, the foundation or back of the picture consists of a stone called piperno. Several oblong pieces, together equal to the whole surface, are taken, each some inches thick, whereby wonderful strength and solidity are acquired, and hollowed to the depth of about three inches and a half, leaving a border all around, with which the work, when completed, will be level. The excavated surface is intersected by transverse grooves, about an inch and a half deep, and somewhat wider at the bottom than the top, in order to retain a quantity of cement or mastic which fills them, the line of the grooves joining in an inclined direction from each side, so as to form an angle in the middle. The separate pieces are then nicely adjusted together, by strong iron cramps behind. Or let it be supposed that a large marble slab is hollowed to the depth of three inches and a half, leaving a projecting and prominent border, the fragments are imbedded in it, to form the picture. This bed or frame is gradually filled with a strong and durable kind of cement or mastic, on the composition of which we shall not here enlarge, both from the general attention now paid to substances of that nature, and because different artists compound them after a different fashion. As the frame is filled, the picture is delineated on the cement, the same way as painting in fresco; and the fragments of enamel being selected for a small portion of it at a time, they are successively beat into the cement with a small flat wooden mallet, until the top of the whole is level, or nearly so. When the artist observes that the fragments so arranged are not suitable to his taste and expectations, he removes them, or substitutes others, which is easily done before the cement hardens, but subsequently it is a more difficult operation. Proper cement remains in a state to receive fragments during fifteen or twenty days, by observing the necessary precautions.

The foundation or back of pictures of smaller size, consists of hammered iron or copper, instead of stone, the surface of which is interspersed with small tin cramps or brackets, like reversed staples, for the purpose of retaining the cement. They are merely slips of metal, bent up at each end, and soldered by the middle to the plate, thus producing inequalities, which operate in the same manner as the grooves of the former Mosaics. The foundation of pavements is of the most solid description, consisting of strong beds of masonry, rising towards the surface of the ground, and are fitted to receive the cement and materials of the representation.

After the whole picture is composed, its surface is ground down to a perfect plane, in a manner similar to what is practised in grinding mirrors, and a polish is given to it with putty and oil. During the progress of these operations, any crevices betrayed at the joints are filled with pounded marble or enamel, mixed with wax, which penetrates by passing a hot iron over them. The kind of polish, however, is regulated by the position and use proposed for the Mosaic, and of late it is not so high as formerly.

Although we have said that cubes or parallelopipeds are employed, the figures are not invariably angular, because curves are sometimes required; and from the ductility of glass, the portions forming a rose, for example, are curvilinear.

Large compositions in Mosaic are tedious, requiring several years to execute; and the grinding and polishing of the surface of a picture are extremely laborious. But it is not necessary that the whole parts should be the work of one individual, as equal skill throughout is scarcely ever indispensable, both because large portions are of a uniform description, and because some may be less artificially arranged. The qualities of Mosaic are various, often being rudely designed, and coarsely executed. Sometimes so little attention is paid to the intimate union of the cubes, that the cement rises between them to form part of the surface, and in general it cannot bear narrow inspection. The most skilful artists, however, have produced works so delicate as to be compared to the finest painting.

From this general description, the substance and structure of Mosaic will be easily understood. It may be carried to an unlimited extent; and in fact spacious pavements, the incrustation of walls, the ornamenting of cupolas, and lining of arches, appear in it in various countries. Italy, always the seat of the arts, engrosses almost the whole Mosaic manufacture of Europe. In

Rome there is a large establishment belonging to the Pope, where this kind of painting is conducted on a great scale. The different materials are arranged in numerous apartments, from which they are removed by the artists as having occasion for them. Besides this establishment, there are many artists in Rome occupied in smaller works, such as pictures, full length figures, whose dimensions do not exceed two or three inches; birds, insects, and baskets of flowers, all in miniature, of exquisite execution. The Mosaics for personal ornaments and toys are innumerable, and they are now common in Britain. The most celebrated modern Mosaic picture has been just completed at Milan, after Leonardi de Vinci's painting of the last supper, preserved in a suppressed convent of that city. This great work is about 24 feet in length, by 12 in breadth, imbedded on 12 slabs of marble obtained from the Lago Maggiore. It is the production of Rafaelli, an artist of the Roman school, by whom eight or ten men were employed on it daily during eight years; and it cost 7500*l.* Sterling. Originally commissioned by Bonaparte, his expulsion is said to have thrown it into the hands of the artist, from whom it was purchased by the present emperor of Austria.

Mosaic appears to greatest advantage at some distance; nor can it be compared in general to the delicacy, smoothness, and uniformity of painting. But its superiority is affirmed to consist in greater durability, and resisting the influence of damp, and the attack of insects; its not suffering from exposure to the sun; in preserving the permanence of colour, and requiring no particular light for embellishment. Yet all these properties are so far counterbalanced by the weight of the materials, tediousness and expense of execution, together with other obstacles, as will prevent Mosaic from competing, in most countries, with painting.

Analogous to Mosaic is the *pietra dura*, or Florentine work, which consists of the union of irregular portions of hard stones containing the gradation of colours in each, instead of obtaining that gradation by the union of multiplied fragments. Some fine specimens of this are preserved at Florence, such as a slumbering Cupid reposing on a lion.

The art of working in Mosaic ascends to high antiquity, and probably preceded painting. It is not obvious, however, as some have asserted, that it was known to the Jews, although that nation was acquainted with singular pavements; for the Koran relates, that when the Queen of Sheba visited Solomon, she was received in a hall where she mistook the pavement for water, and bared her limbs; on which Solomon said, "the floor is solid: it is made of glass." Likewise, amidst the wonders beheld by John, in the Revelation, was "a sea of glass like unto crystal." But other eastern nations were acquainted with Mosaic; for in the palace of Ahasuerus was "a pavement of red, and blue, and black marble," *Esther*, chap. i. v. 6. Ciampini, an author who has bestowed much investigation on this subject, ascribes the invention of Mosaic to Persia, of which there does not seem to be satisfactory evidence; and it must be admitted that there is considerable uncertainty as to the precise country over which Ahasuerus reigned.

The name *Mosaicum*, *Musiacum*, or *Musivum*, was first employed only towards the fourteenth century; and the words *pavimenta Lithostrata*, *sectilia*, *secta*, or *tesselata*, were used to denote mosaics properly so understood by the ancients. Thus it is affirmed that the painted floors of the Greeks gave way to mosaic; and Pliny observes, that *Lithostrata acceptavere jam sub Sylla parvulis certe crustis extat hodieque, quod in Fortunæ delubro Praeneste fecit. Pulsa deinde ex humo pavimenta in cameras transiere e vitro*, lib. xxxvi. cap. 60, 64. Athenæus speaks of the rich pavements in the palace of Demetrius Phalereus, lib. xiii. § 60; and Hiero, king of Syracuse, is said, by the same author to have had an extraordinary ship constructed, in which the tesselated pavements of the cabins represented the whole fable of the Iliad, lib. v. § 41. Thus the art was familiar to other nations as well as to the Romans, from whom our acquaintance with it is derived. Isidorus afterwards designs real mosaic very distinctly, by *lithostrata parvulis crustis ac tessellis junctos in varios colores*—*De Origin.* lib. xv. cap. 8. *Pavimentum sectile* was composed of large compartments of marble; *sectum* merely of alternate square pieces; *tesselatum*, or *quadratorium*, from the word *tessera*, a die constituted real mosaic, of small cubes of glass or marble; and the *pavimentum vermiculatum*, consisting of the same, received that name only from its peculiar figure. Learned foreigners remark, that it is only in Britain that the correct designation of mosaic is preserved in *tesselated pavement.* The art of colouring glass practised in the age of Augustus, greatly promoted the use of mosaic; it became so common, that at length, Seneca, reproaching the luxury of his cotemporaries, complains, that they seemed unwilling to tread, unless upon precious stones. *Eo deliciarum pervenimus ut nisi gemmas calcare nolimus*, Ep. 86.

From the Romans it spread into their provinces, and as they had the sovereignty of Europe, there are few countries where relics of Mosaic are not now discovered. Justinian also decorated the church of St. Sophia, in Constantinople, during the sixth century, with works of the same kind, which are partly doublets or pieces of glass united horizontally, with a coloured foil interposed, as may be seen at this day. Some of the earliest popes decorated the churches of Italy with Mosaic, but the art declining there from the fifth or sixth century, is believed to have been almost totally lost, until Andrea Taffi learned it from a Greek artist Apollonius, who was employed on the church of St. Mark, at Venice, in the thirteenth century. This is to be viewed as the source of the modern Mosaic, which, as we have observed, has attained an infinitely greater perfection in some respects than that of the ancients, and has been carried to a great extent. The names of few of the ancient artists have come down to us, but among others those of Dioscorides, a Samian, and Archimedes, a Syracusan, are preserved. Many of the moderns are celebrated, from Giotto in the fourteenth century down to Tucca in the sixteenth; Mancini, Calandra, Lafranc, in the seventeenth; Cristofori, Brughi, Calendrelli, Camucci, and many more in the eighteenth and nineteeth.

The price of Mosaic depends on the quality and extent of the work, in which there is as great a difference as in any paintings. Pictures of large size have cost £5000, £6000, or more. Small personal ornaments or toys can be obtained for a few shillings. There are masters in Mosaic as well as in painting.

The greater Mosaic works of the ancients probably were devoted to their halls and baths, while that of the moderns is employed in churches. None of the former are found entire, or with the rarest exceptions, but portions are frequently disclosed in the course of excavation, which enable us to judge sufficiently of the extent, design and execution of them. Some persons erroneously suppose that the colour of stones and marble is permanent, but it fades in both, almost without exception, on long continued exposure in the air.

One of the finest ancient Mosaic pavements extant, was discovered at a village near Seville in Spain, in the year 1799, at the depth of three feet and a half from the surface, from a brief description of which the nature of others may be comprehended. It extends above 40 feet in length, by nearly 30 in breadth, and contains a representation of the circus games in a parallelogram in the centre, three sides of which are surrounded by circular compartments, containing portraits of the Muses, interspersed with the figures of animals, and some imaginary subjects. In the race course are seen a chariot overturned, the charioteer thrown out of his seat, horsemen dismounted, fractious steeds, and broken harness. The charioteer, having been injured by his fall, is supported by two men belonging to a different faction or party, as may be ascertained by their costume, which, in all the figures, is well represented; the horses are of a deep brown colour; they have a cut tail like our modern fashion, and are apparently full of spirit. Various persons interested in the games appear in other portions of the course, and beyond it; but part of the whole pavement has been destroyed, by the waste of time and the injury of the workmen by whom it was discovered. A double row of circular compartments bound the sides of the course, some of which are very entire. Each is about three feet and a half in diameter, ornamented by a broad circular border as a frame. The whole plan is finished by an exterior border, highly embellished. Nine of these compartments are occupied by busts of the nine muses, arranged after the manner prescribed by Hesiod, and in the order of the books of Herodotus, but alternately, so that a compartment containing a mask, or an animal, or some other subject, is always interposed between two. The name of each muse is inscribed in her respective compartment, and several have their respective attributes, concerning which antiquaries have been frequently at variance, nor is it probable that the ancients themselves absolutely coincided on the subject. Calliope has a book, Polhymnia a lyre, those of Erato and Terpsichore are not equally obvious. The countenance of the muses is handsome, deep brown, as if belonging to a southern climate, with regular features, and fine large animated eyes. All have darker or lighter auburn hair, artificially disposed after different fashions, and some have ornaments on the head. They have for the most part a cloth thrown over an under garment, the latter appearing in Urania to be a robe.

The other compartments are occupied by a centaur, the genius of the circus games; children in different-coloured tunics, representing the seasons; and animals either finished or outlined. The floor also between the different compartments exhibits various birds, fruits, and flowers. Great diversity of colour is seen in this mosaic, without that delicate and regular degradation, however, which is employed by the moderns; but we are compelled to refer the reader to the splendid work of M. Laborde on the *Mosaics of Italica*, for further illustrations of this composition. The pavement is supposed to have belonged to the hall of the baths of a palace or city of that name, which was founded 208 years before Christ, and that it was constructed anterior to the reign of Domitian.

In the year 1806, a fine mosaic pavement, of lesser dimensions, but relative to the same subject, was discovered at Lyons, which M. Artaud ascribes to the first century of the Christian era. It is composed of small marble cubes, sometimes interspersed with pastes of different colours; and extends fifteen feet and a half in length, by nine and a half in breadth, exclusive of an ornamental border. The whole details of the games of the circus are represented here, from which it appears that no less than eight chariots started at a time, some of which are broken, and the horses and charioteers have fallen, as in the mosaic of Italica; for it was a point of address among the ancients to overthrow their competitors in the course. Some of their horses are white, grey, or pale bay; their figures are elegant and animated, and they exhibit "a cut, set tail, after the English fashion." A number of persons, in their peculiar costume, seem to have a share in the games; and in general those presiding are clothed in blue, which M. Artaud conjectures to have been the national colour of the Gauls. From this and the preceding mosaic of Italica, several passages of the classical authors are illustrated, which have hitherto embarrassed antiquaries. Artaud, *Description d'un Mosaique*.

The ordinary subjects seem to have been the Circensian games, theatrical scenes, marine deities, tritons, and nereids, all as requiring a large space, and adapted to the situation. Nothing has been more celebrated, on another scale, than three pigeons washing themselves, and a fourth drinking from the vessel, composed of marble fragments, not exceeding a line square, and adjusted with admirable precision. Many of the ancient mosaic works, we have seen, were devoted to the embellishment of halls and baths, and exhibited lively representations; but with the decay of the Roman empire, they were employed in the decoration of churches, and their subjects altered to those of a grave character. On the roof of the baptistery of the church of St. John at Ravenna, the baptism of Jesus Christ is represented in mosaic, ascribed to the fifth century. The ceremony is performed partly by sprinkling, and partly by immersion. A circular compartment in the centre is occupied by Christ standing upright in the river, and John, holding a long misshapen cross in one hand, pours water from a shell, or some vessel, on his head with the other, while a dove descends above the former. It likewise contains a human figure inscribed *Jordann*, rising out of the water, which is probably a personification of the sacred river. This compartment is environed by full length figures of the twelve apostles, and the whole is surrounded by a border, consisting of pulpits, altars, and other subjects.

The church of St. Peter's at Rome, contains the most extensive collection of modern mosaics extant, whether in decorating the cupolas, tombs, or altars. There are many pictures of large size, after the paintings of Raphael, Guido, Carlo Maratti, Guercino, and other great masters, representing either portions of scriptural history, the miracles of later saints, or events of their lives. It is here that, the works of distinguished artists being accumulated, we are enabled to judge of their respective talents. Independent of these, many ancient mosaics are to be seen in other churches, and in the various museums of that city.

With respect to the mosaics which have been discovered at different times in Britain, which was so long a Roman province, sufficient information will be found in the *Archæologia*, and *Monumenta Vetusta*, another work published by the London Society of Antiquaries, and the works of Mr. Lysons; and for an account of mosaics in general, the treatises of *Ciampini* and *Furietti* may be consulted. See also Cadell's *Travels in Carniola and Italy*, vol. i. p. 517, vol. ii. p. 202, and the *Edinburgh Philosophical Journal*, vol. ii. p. 348, and vol. iii. p. 419. A very splendid work on mosaics is now publishing by M. Artaud of Lyons. (*c.*)

MOSAMBIQUE, or MOZAMBICO, an island on the east coast of Africa, and the capital of the Portuguese settlements in that quarter. This island, which resembles a crescent, with the hollow part towards the sea, measures about two miles and a half in length, and a quarter of a mile in breadth. It is situated in 15° 10′ S. latitude, and 41° E. longitude, in the mouth of a bay nearly three miles in circuit, which furnishes a safe and convenient haven for shipping. On the north extremity of the island is a strong fort of an octagonal form, furnished with six bastions, and containing 80 pieces of cannon, besides a large howitzer, capable of casting stones of 100 lbs. weight. The situation is well chosen, and more than thirty of the guns bear upon the entrance into the harbour. In 1608, it resisted a vigorous attack of the Dutch, who landed in considerable force upon the island; and, after three weeks of unavailing exertion to reduce the place, were compelled to reimbark with loss. The anchorage is on the north-west side of the island, on a flat level sand, well protected from the sea, and within a musket-shot of the shore, where there is a very commodious landing-place, with steps on either side of a pier, which extends a considerable way into the sea. Immediately opposite to the anchorage lies the town of Mosambique, occupying the central part of the island, and presenting, in the appearance of its buildings and inhabitants, a strange mixture of Indian, Arabian, and European costume. The soil of the island is sandy, and tolerably fertile, yielding rice, millet, pulse, roots, &c.; but the settlement depends for its supplies on the peninsula of Cabaceiro, a tract of land about eleven miles long, and four broad, connected with the continent by an isthmus about a mile across, which could be easily rendered secure against any attack from the interior, were it not that the creek on the south side becomes dry at low water for the space of nearly four miles. On this peninsula are several villages and plantations, but none of them displaying much agricultural industry or skill. The principal trees are the cocoa-nut, cashew, mango, papaw, and orange; and the chief article of cultivation is the manioca root, which constitutes the food of the slaves. A great part of the land still remains uncultivated; but numerous herds of cattle, and vast droves of swine, are reared upon its pastures. A great variety of birds frequent the groves; and the most curious sea productions abound on the coast, such as star-fish, and sea-flowers of uncommon beauty, sponges of several kinds, sea-priapi, molluscæ, muscles, crabs, and oysters, which are said to yield pearls of considerable value. The beach is covered with flamingoes, spoonbills, curlews, snipes, and larks; large herons, and several species of gulls; and great numbers of slaves are generally seen at low water employed in collecting the shell-fish. One of the most remarkable of the fishes found on the coast, is the sucking-fish, or remora, which is said to be employed in catching turtles in the following manner: When fastened to the boat with a line, it invariably darts forwards, and fixes itself by its sucker to the first turtle which it meets, holding so strongly as to enable the fishermen to secure the prey.

The climate of Mosambique, from its oppressive heat and heavy atmosphere, is extremely unhealthy; and its fatal effects are so much increased by the mode of living, that both among the military and civilians, not more than seven out of a hundred are calculated to survive after a service of five years. With the exception of the governor and his staff, the greater part of the European settlers are culprits, who have been sentenced to banishment. The native planters, descended from the old settlers, have, in consequence of their dealing in slaves, become vicious, indolent, and careless of improving their plantations. Another class consists of the descendants of the old Arab settlers, most of whom are engaged in a seafaring life, and Banian traders and artizans. The remainder of the inhabitants is composed of the free blacks and native soldiers; and the whole population is calculated at little more than three thousand, of which the last mentioned class composes one half, and the two other classes about one fourth each. The European Portuguese and natives, are generally persons of little respectability and debauched morals; and the chief employment of both consists in the traffic of slaves, which renders them not very scrupulous about the means of gaining wealth. The regular salaries of all the public functionaries are so utterly inadequate for their support, that they are too much tempted to tolerate various abuses, such as selling the inferior offices of command, reducing the effective force of the settlement, and sharing in the perquisites which arise from the nefarious trade in slaves. This trade used formerly to supply the Cape of Good Hope, the Isle of France, and Batavia, with almost the whole of their slaves; besides sending a considerable number to the East and West Indies. Great part of this traffic is cut off by the abolition of the trade on the part of Great Britain; but still the settlement supplies the Brazil coast and Spanish colonies with above 4000 of these unfortunate creatures every year. They are bought at the rate of four or five pounds a head; and it is reckoned a lucky voyage, if, out of a cargo of 300 or 400, only 60 die in the passage to South America. To the Portuguese colonies in India, they send annually four or five vessels loaded with gold, ivory, and slaves, which bring back in return cottons, teas, and other kinds of eastern produce. All exports are exempted from duty, except slaves, which pay at the rate of 16½ crusades each. Imports, after all charges are included, pay about 25 per cent., except specie, which pays 2½, of which one per cent. goes to the revenue, and the rest to the governor. The most suitable articles for the market of Mosambique are iron bars, and hoops, lead powder, shot, cutlery, stationary, prints, and framed pictures, some articles of household furniture, cotton for sofas, silk and cotton stockings, shoes and boots, waistcoat pieces, light plain muslins, blue cloth, a few telescopes, salt butter, hams, and cheese, and a little of most articles of luxury in use among the Portuguese. Most of the goods for exportation bear a high price; but vessels may be supplied with provisions, consisting of bullocks, goats, and guinea-fowls, at a moderate rate. A considerable number of an Arabian breed of asses is also reared at Mosambique for exportation, which are generally sent to the Brazils as presents, but which fetch a high price when sold.

The articles exchanged with the Africans for their gold, ivory, and slaves, are chiefly salt, shells, beads, tobacco, coloured handkerchiefs, and coarse cloths from Surat.

It is a peculiar custom in the colony, that every person who can command a decent dress may visit the governor's house in the evening, which many take care to do, chiefly for the sake of obtaining a cup of tea; and whenever the governor removes to his country seat, it is esteemed a proper mark of respect to follow him, and make similar visits of ceremony. The wives of the planters (of whom few are seen in public) are generally thin and sallow in their complexion, negligent in the care of their persons, except on great occasions, and resembling those of the Cape in their taste for smoking tobacco, and the custom of going without stockings. The food of these planters is gross in the extreme, consisting of great masses of boiled meats, chiefly pork and beef, in the midst of vegetables; with quantities of oil, not remarkable for its purity, in most of their dishes.

The natives who occupy the country behind Mosambique, are the Makooa or Makooana, comprising a number of powerful tribes, extending northward as far as Melinda; southward, to the mouth of the Zambezi; and in a southwest direction, almost to the neighbourhood of the Caffres. They are an athletic and ugly race of people, of the most ferocious aspect, and savage disposition. They are fond of tattooing their skins, and draw a stripe down the forehead along the nose to the chin, which is crossed in a direct angle by another line from ear to ear, so as to give the face the appearance of being sewed together in four parts. They file their teeth to a point, so as to resemble a coarse saw; and suspend ornaments of copper or bone from a hole in the gristle of the nose. Their upper lip protrudes in a very remarkable degree; and this they consider as so principal a point of beauty, that they endeavour to make it still longer, by introducing into the centre a small circular piece of ivory, wood, or iron. They dress their hair in a very fantastic manner, some shaving one side of the head, others both sides, leaving a kind of crest from the front to the nape of the neck; while few of them wear simply a knot of hair on their foreheads. Their females resemble greatly the Hottentot women in the curvature of the spine, and protrusion of the hinder parts; and, when past the prime of life, are said to present the most disagreeable objects that can be conceived. They are fond of music and dancing; but their tunes and motions are unvaried and monotonous. Their favourite instrument is called Ambira, which is formed by a number of thin bars of iron of different lengths, highly tempered, and set in a row on a hollow case of wood, about four inches square, and closed on three sides. It is played upon with a piece of quill; and its notes, though simple, are sufficiently harmonious, sounding to the ear, when skilfully managed, like the changes upon bells. They are armed with spears, darts, and poisoned arrows; and possess also a considerable number of muskets, which they procure from the Arabs in the northern districts, and sometimes even from the Portuguese dealers. They are formidable enemies to the settlement; and have been rendered desperate in their hostilities, by the nefarious practices of the traders who have gone among them to purchase slaves. But, notwithstanding this natural ferocity, they are very docile and serviceable as slaves; and when partially admitted to freedom, by being enrolled as soldiers, they become both expert and faithful in the service. A few tribes on the coast, who speak the same language as the Makooa, and probably belonged originally to the same stock, had fallen under the jurisdiction of the Arab settlers; and, when these last were conquered by the Portuguese, became bound to pay tribute, and render military service. Their Sheiks are appointed by the governor of Mosambique; and some of them are so powerful as to be able to bring into the field from two to four thousand men; but as they seldom act in unison, little reliance can be placed on their assistance.

This coast had been known to the Arabs, and its ports frequented by their traders, for centuries before its discovery by Europeans; and all the information possessed by the latter on the subject, was chiefly drawn from the vague accounts of Ptolemy, and the Periplus of the Erythrean sea. It was first discovered by the Portuguese in the year 1497, who found the whole of the coast in the possession of the Arabs; but the fame of its gold mines, and the convenience of its ports, as resting places for the Indian trade, led them to attempt the expulsion of the original settlers. This was easily accomplished by their superiority in arms; and, in 1508, they had conquered Quiloa, gained a footing in Sofala, and built the fort which still stands on the island of Mosambique. They gradually encroached on the Mohammedan possessions in the river Zambezi; and, about the year 1569, they completely cleared that part of the river of the Arabs, by putting the whole of them to death. In the attempts of the Portuguese to reach the gold mines of the interior, they were not very scrupulous as to the means which they employed; and have furnished, in the history of the East, a parallel to the atrocities of their Spanish neighbours in the West. But theirs was a harder task; and the natives of Africa maintained a nobler struggle for the independence of their country, than the feebler South American race. Though compelled to abandon their fields and habitations to the rapacious invaders, they embraced every opportunity of harassing the enemy in their progress, or of taking them by surprise in their settlements. The most celebrated of these expeditions was undertaken at the command of Sebastian I. in 1570, and conducted by Francis Baretto, who had been purposely appointed governor-general of Mosambique. They penetrated the country of Monomotapa, and burnt its capital; but, after losing a great number of men, they were obliged to retreat with no other fruit of their victories, than permission to pass through the territories of Monomotapa, upon condition of paying an annual tribute of 200 pieces of cloth. Another attempt was soon after made through the country of the Mongas or Monjou; and, after a hard fought battle with the natives, the armament passed the forest of Lupata, and then, marching eastward along the line of the Zambezi, made every exertion to reach the silver mines of Chicova; but all their researches proved fruitless; and a detachment, which had been left behind to prosecute the object, was cut of by an ambuscade. Since this event, the Portuguese have contented themselves with acting on the defensive, occupying the coast along the line of the river Zambezi, and maintaining their influence in the country, by exciting the native powers against one another. Even in these limited views, they had many hard contests with the natives, and particularly in 1589 and 1592, they were attacked on the northern bank of the last mentioned river, by a wandering and ferocious tribe named Muzimbaj, who afterwards passed eastwards, and are conjectured to have belonged to the tribes of Galla, who penetrated to the frontiers of Abyssinia. The Portuguese were not more successful in attempts to convert the natives to the Catholic faith; and, though one of their most zealous missionaries, Gonzalvo de Sylva, gained access to the court of the Prince of Monomotapa, and made a favourable impression on his mind, the Mahomedan traders afterwards acquired the ascendancy, and effected the destruction of the Portuguese teachers. Most of their other converts, as has too ofen been the case in catholic missions, were merely nominal, and little benefited by the appellation of Christians. The value of this colony to Portugal has always been greatly overrated, but was probably greater in former times than it can be at present. It furnished large supplies of gold and ivory, and enriched at least a number of private individuals, whose wealth ultimately proved beneficial to the state. It afforded in the earlier voyages to the east an important resting place, and supplied most of the Portuguese colonies with slaves. Its trade and importance have naturally declined with that of the mother country, and especially with the loss of her eastern possessions; but the impolitic manner in which it has for a long time been governed, has farther reduced it to a state of weakness and insignificance which can scarcely withstand the attacks of the surrounding savages. During the war with France, and before the capture of the Mauritius by the British, it suffered greatly from the French privateers, and has recently been exposed to serious depredations from the tribe of pirates called Marati, who occupy the north-east point of Madagascar. See Purchas's *Pilgrim*; Salt's *Voyage to Abyssinia*; and *Histoire de l' Ethiopie Orient. par* C. R Jean des Santes. (*q.*)

MOSCOW, formerly the metropolis of the Russian empire, is situated in East Long. 37° 33′, and North Lat. 55° 45′ 45″. It was founded by George, son of Volodimir Monomaka, who ascended the Russian throne in 1154; but it was Daniel, the son of Alexander Neuski, who, by making it his residence as duke of Muscovy, laid the foundation of its future greatness, and, in 1304, made it the capital of the Russian dominions. In 1382, it was taken by Tamerlane, after a short siege, but soon came again into the possession of the Russians. It was frequently occupied by the Tartars, during the 14th and 15th centuries; but they were finally expelled by Joan Vassilievitch I. who rendered Moscow the principal city of the empire. It continued to be the metropolis of Russia till the beginning of the eighteenth century, when the seat of empire was transferred to Petersburgh; but it still continued to be the most populous city in the empire, and the residence of those nobles who did not belong to the court, and delighted to exhibit their ancient feudal grandeur. It stands in the midst of a fertile plain, watered by the river Moskwa, which flows round the greater part of the city. It is about twenty-six miles in circumference, and covers twelve times the area of Petersburgh. It does not contain, however, above 300,000 inhabitants, of whom about 50,000 are retainers and domestics of the nobles, who make their residence in the town only during the winter season. Its appearance, from a little distance, is very singular and splendid, presenting a numerous assemblage of spires glittering with gold, amidst burnished domes, and painted palaces.

There is no outer wall around the city, but only a simple parapet of earth. After entering this enclosure, the city seems to have disappeared, and nothing is seen but a wide scattered suburb, composed of "huts, gardens, pig-sties, brick-walls, churches, dung-hills, palaces, timber-yards, warehouses," &c. "One might imagine," says Dr. Clarke, "all the states of Europe and Asia had sent a building, by way of representative, to Moscow; and under this impression, the eye is presented with deputies from all countries, holding congress; timber-huts from regions beyond the Arctic; plastered palaces from Sweden and Denmark, not white-washed since their arrival; painted walls from the Tyrol; Mosques from Constantinople; Tartar temples from Bucharia; pagodas, pavilions, and virandas from China; cabarets from Spain; dungeons, prisons, and public offices from France; architectural ruins from Rome; terraces and trellises from Naples; and warehouses from Wapping." The general aspect of the buildings is a mixture of gothic and modern architecture: or rather that of a city built upon the Asiatic model, but gradually becoming more European. Many of the palaces, instead of a single structure, are formed of a vast assemblage of buildings, distributed into several streets, and bearing the appearance of a moderately-sized town. The streets are very long, and generally broad; but frequently narrow and dirty. Some of them are paved; but the greater part are merely floored with trunks of trees or plants, and covered with mud and dust. There is an endless variety in the style of the different buildings. Some of the wooden-houses are painted; many of the brick structures have wooden roofs, and others have iron roofs and doors. The churches, which are very numerous, have their domes of wood, or copper, or tin, gilded, or painted green. Nor are the different edifices assorted with any kind of uniformity; but wretched hovels are blended with spacious palaces; and cottages of one story stand next to the most superb and lofty mansions. "In a word," says Mr. Coxe, "some parts of this vast city have the look of a sequestered desert, other quarters of a populous town; some of a contemptible village, others of a great capital." "Or," as the Prince de Ligne has described it, "Moscow looks exactly as if three or four hundred great old chateaus had come to live together, each bringing along with it its own little attendant village of thatched cottages."

Moscow contains five distinct divisions or towns, each surrounded by its own wall, viz. the Kremlin, or fortress; the Kataigorod, or Tartar town; the Bielgorod, or White town; the Semlianogorod, or Circular town; and the Slabode, or Suburbs. The two first are situated on a central eminence, and are placed side by side; but around them lies the third town in a circle, which is in like manner surrounded by the fourth; and that again by the fifth, marking, by their several lines of circumvallation, the growth of the place in successive æras. 1. The Kremlin, which is of a triangular form, and about two miles in circumference, contains the citadel, with several churches and magnificent houses; and particularly the palace of the Czars, a building in the Hindoo style, above 200 years old, and one of the most gorgeous pieces of architecture in the city. This part of the town presents an assemblage of bright gay colours and gaudy ornaments; the cupolas and roofs being gilt, or stained with green and red; the walls and towers covered with glazed tiles of blue, white and yellow, or paintings of the Scripture history; a melange in short on every side of "peer-shaped domes, Tartar battlements, gothic tracery, Grecian columns, the star, the crescent, and the cross." 2. The Kataigorod, larger than the Kremlin, contains the University, the printing-house, several public buildings, the tradesmen's shops, and the only street in Moscow in which the houses stand close to each other. 3. The Bielgorod; and 4, the Semlianogorod, exhibit a strange mixture of churches, convents, palaces, brick and wooden houses, and even mean hovels like the cottages of the peasantry; and the 5, Slabode, is a vast irregular circle, surrounding all the other parts, and containing all kinds of buildings, besides corn fields, pasture grounds, and some small lakes, which give rise to the river Neglina. The churches in Moscow are very numerous; and, including chapels, are not less than 1000. Many of them, built of brick, are stuccoed or white-washed; but the greater part are constructed of wood, which is painted of a red colour. The most ancient of these edifices are generally of a square form, with a cupola and four small domes of copper or iron gilt, or of tin painted green. These cupolas and domes are usually ornamented with crosses, entwined with chains or wires. In the body of these churches, there are usually four square pillars supporting the cupola; and these, as well as the walls, are covered with paintings of enormous figures, and of rude execution. Over the door of each church is the portrait of the saint to whom it is dedicated, to whom the common people pay respect as they pass by, taking off their hats and crossing themselves, or sometimes by repeatedly touching the ground with their heads.

The bells which are amongst the most remarkable objects to be noticed in Moscow, are hung in belfries detached from the church; and are rung by a rope tied to the clapper. Some of these bells are of extraordinary size, and yield the most solemn tones. One of them in the belfry of St. Juan, is above 40 feet in circumference, and more than 57 tons in weight. "When it sounds," says Dr. Clarke, "a deep and hollow murmur vibrates all over Moscow, like the fullest and lowest tones of a vast organ, or the rolling of distant thunder." But the great bell of Moscow, the largest ever founded, is in a deep pit in the midst of the Kremlin, where it was originally cast. It never was suspended; and in consequence of water having been thrown in to extinguish a fire in the building erected over it, a large fracture was made in the bell. It has a white shining appearance, and is said to contain a very large proportion of gold and silver. The size of the base cannot be ascertained, as it is partly buried in the earth; but the circumference, within two feet of the lower extremity, is sixty-seven feet four inches; and the perpendicular height from the top twenty-one feet four inches and a half. In the stoutest part, about seven feet above the lip of the bell, where it should have received the blow of the hammer, it is above twenty-three inches thick; and the weight of the whole is computed to be 443,772 lbs. which at three shillings a pound amounts in value to 66,565*l.* 16*s.*

Another wonder of the Kremlin is the great gun, which admits of a man sitting upright in its mouth, and is about 18½ feet in length, and 10 inches thick at the lip. It is never used, and serves merely for ostentation; but it is surrounded with artillery of extraordinary length. One of the principal structures and public institutions of Moscow, is the Foundling Hospital, an immense quadrangular pile of building, capable of containing 8000 children, who are suitably instructed according to the occupation which they are desirous to follow, and who receive, at the age of 20 years, a sum of money, with various advantages for prosecuting their trade in any part of the empire. This institution, besides diminishing the practice of child-murder, (which is said to have been greatly prevalent before its establishment) diffuses the knowledge of the arts among the people, and increases the number of free subjects in the empire. All the shops of Moscow are collected together in one spot, in the division of Kataigorod, where the whole retail commerce of the city is carried on, and where there is the appearance of a perpetual fair. Every trade has its separate department; but the shops which sell fur and skins, occupy the greatest number of streets. There is a market held in a large open space, in one of the suburbs, where ready made houses of every variety are strewed upon the ground, and where a purchaser, upon specifying the number of rooms which he requires, may have a dwelling removed, raised, and occupied in the space of a week. The number of picture-dealers in Moscow is very great; and the houses of the nobles are filled with them; but they are almost all copies made with the most exact imitation, and in general are valued according to the splendour of the colouring, and fineness of finishing. The booksellers' shops, also, are seldom provided with books of real literary reputation, but are rather stored with toys than the instruments of science. The splendour of the equipages, and the number of horses attached to them, gives an appearance of wealth and grandeur far above the reality. There is hardly an individual above the rank of a plebeian, who has not four horses to his carriage; the greater part have six; but the postilions are generally ragged boys, and the coachman a peasant in his sheepskin, while the long traces of the horses are made of no better materials than ropes.

In the metropolis of an empire composed of so many different nations, rather united than assimilated, the manners, dresses, amusements, languages, and occupations of the inhabitants, present to the eye of a stranger the most wonderful variety. The amusements are of the most childish description; and the most respectable of the citizens, and even persons of rank, may be seen in public, whirling about in chairs, and screaming with pleasure. One of the most general luxuries, is that of the bath, which is taken in public, both by men and women, who may often be seen naked before these places of resort, talking together without any sense of shame. The citizens are fond of promenades, which, particularly during Easter, take place every morning and evening; and in which, besides the nobles in their carriages and on horseback, are seen the merchants' wives on donkies in their richest dresses, the peasantry shouting and singing, the gypsies dancing, piping, clapping of hands, and various kinds of revelry. Another favourite resort is the market on Sunday mornings, in a spacious area near the Kremlin, where people of every description assemble to purchase dogs, singing birds, peacocks, poultry, fire arms, curious pigeons, &c. Dogs and birds are the principal articles, and particularly the pigeons, in which the nobles of Moscow take great delight, and which are trained by the feeders to fly and return at command. The morals of this great city are extremely relaxed; and it is no uncommon thing for a number of hired prostitutes to be kept openly in the inns for the use of the guests.

Hitherto we have spoken of Moscow, as it existed previous to its occupation by the French army under Buonaparte in 1812; but, by the conflagrations to which it was devoted, both by the Russians and the French, at their respective evacuations of the city, it was almost entirely destroyed, except some of the more distant parts of the Slabode, where the houses were thinly scattered, and a few streets in the division of Bielgorod, which had been occupied by the French guards. Preparations were made, by Buonaparte's orders, to blow up the Kremlin; but, excepting one of the towers, and the church of St. Nicolas, the greater part of it was preserved by the exertions of the Russians. By official returns before the conflagrations, the wooden houses amounted to 6591, and those of stone or brick to 2567. When the French evacuated the town, there remained of the former only 2100, and of the latter 526. In the year 1814, there were refitted in wood 1480, and in stone or brick 1312. During the summer, when the weather permitted the people to bivouac in the streets amidst the ruined houses, about 170,000 inhabitants were collected; but the residence of this number could not be counted upon during the winter. Its appearance at that period is thus described by an intelligent English traveller. "It was from the road, as it passed under the turrets of the Petrousky palace, that we first beheld the myriads of domes and steeples that yet glittered among the ruins of Moscow; and a short hour brought us to the barriers. At our first entrance, few symptoms were seen of a nature to correspond with the gloomy appearance which we had been led to expect; but, as we advanced, the quarters of the Slabode or Fauxbourg, where wood had chiefly been used in building, exhibited destruction in its fullest extent, for the most part, a *champagne rasé;* now and then the shell of a house was seen standing in a blank space, and here and there a few bricks and stones yet remaining, pointed out the spot where a dwelling once had been. Moving onwards, we crossed the avenues of the boulevards; the trees were in full leaf and beauty, seeming to vary the view only to heighten its melancholy aspect. Leaving this, we passed to the central parts of the town, that were constructed with more durable materials, exhibiting occasionally a richness and elegance of exterior, that must have equalled, if not surpassed, the architectural magnificence of the most beautiful towns of Europe. But all was now in the same forlorn condition; street after street greeted the eye with perpetual ruin; disjointed columns, mutilated porticos, broken cupolas, walls of rugged stones, black, discoloured with the stains of fire, and open on every side to the sky, formed a hidious contrast with the glowing pictures which travellers had drawn of the grand and sumptuous palaces of Moscow. The cross lanes looked, even at this interval, as if unused to hear the sound of human tread: the grass sprung up amidst the mouldering fragments that scattered the pavements, while a low smoke, issuing perhaps from some obscure cellar corner, gave the only indications of human habitation, and seemed to make desolation "visible." See Coxe's *Travels in Russia;* Clarke's *Travels*, vol. i.; and James's *Travels*, vol. ii.

MOSES, the inspired lawgiver of the Jews, was the son of Amram and Jocabed: and was born in Egypt, A. M. 2433, and B. C. 1571. His name signifies "drawn out;" and was given to him by the daughter of Pharaoh, because she had drawn him out of the water. Being adopted by this princess, he was instructed in all the learning of the Egyptians, and spent the first forty years of his life at the court of her father. He is said by Josephus to have commanded the army of the Egyptians, in an expedition against the Ethiopians, whom he defeated and subdued. The next forty years of his life he passed in the land of Midian, where he took refuge from the vengeance of Pharaoh, and where he married the daughter of Jethro, the priest of that country. The last forty years of his life were employed in conducting the people of Israel to the land of Canaan, on the borders of which he died, in the 120th year of his age. The particulars of his history are so much connected with that of the Jewish people, and are so well known, by means of the sacred Scriptures, that they need not be detailed in this place. Little dependence can be placed upon the accounts given of him by Josephus, Philo, the Jewish Rabbins, and various profane authors; and it is only in his own writings, that any thing authentic can be found respecting his extraordinary character and miraculous services. The frequent notice, however, that is taken of him by many ancient writers, serves to confirm the truth of his own narrative, and to point him out as the most ancient author, of whom any authentic works remain. He is thus mentioned by Manetho, Cheremon, Apollonius, and Lysimachus, as quoted by Josephus against Appian, l. i. § 26 and 32.; by Eupolemus and Artapanus, as quoted by Eusebius. Prop. Ev. lix. c. 26—20.; by Strabo, Geog. lxvi.; by Trogus Pompeius, in Justin. hist. lxxxvi. c. ii.; by Pliny the elder, Nat. Hist. l. xxx. c. i.; by Tacitus, hist. l. v. c. iii.; by Juvenal, Sat. xiv. v. 96.; by Longinus on the Sublime, § 9.; by Numenius, as cited by Origin against Celsus, l. iv. p. 198.; by the author of the Orphic verses, a production of great antiquity; by Diodorus Siculus, l. i. who mentions Moses as one who ascribed his laws to the God Jaoh, which may be considered as a corruption of the name Jehovah, and also in his fortieth book, as preserved by Photius, Bib. No. 244, he speaks of him as a man of illustrious prudence and courage; by Poleman, Appion of Possidon, Ptolemy Mendesius, Hellanias, Philocorus, Castor, Thallus, and Alexander Polyhistor, as enumerated by Justin Martyr, Cohort. ad Gent. p. 9—11.

Some of the Psalms, particularly the xc. have been ascribed to Moses; and also the book of Job, or at least the rendering of it from the original Arabic into the Hebrew language. But these are no more than mere conjectures; and the only unquestionable writings of Moses, are the first five books of the Old Testament, generally called the Pentateuch, and which are supposed to have formed originally but one book.

The Editio Princeps of the Pentateuch, was published with the Hebrew Bible, printed at Soncini, 1488; and the first translation into English, by William Tindale, was printed at Marlborow, in the land of Hesse, by Hans Luft, 1530, and at Hamburgh in the same year. (*q*.)

MOTION. See Dynamics and Mechanics.

MOULINS, a town of France, and the capital of the department of the Allier, is situated in a fertile plain, on the right bank of the river which gives its name to the department. Moulins is divided into the old and new town, and has two suburbs. The streets are in general broad and well paved, but the houses look ill, from being built of differently coloured bricks. The principal public buildings are, the Military School, the Chateau, the Tower of Jacquemarre, the Churches of Notre Dame, the Carmelites, and the Jacobins, the Caserne, and the Bridge. The Military School is a splendid building on the north side of the town, is two stories high, has 28 windows in the length of its front, and a noble Ionic portal. The chateau, of which a part only remains, is now a prison. The tower of Jacquemarre, from which there is a fine view of the town, of the beautiful gardens of the Bercy, and the surrounding country, is merely a tower for a clock, on which the hours are struck by two men. The church of Notre Dame, which has never been finished, is handsome, with five buttresses, but has suffered much during the Revolution. Behind the altar is a fine representation of our Saviour's sepulchre. The church of the Convent of St. Marie, situated beside the military school, has a neat portal, but is remarkable chiefly for the tomb of the celebrated Duke de Montmorency, who was beheaded in the reign of Louis XIII. It is a splendid specimen of sculpture in marble, by Covsto. The remains of the duke and his duchess are deposited in a noble sarcophagus of black marble, with a simple inscription. Above the sarcophagus are recumbent statues of the duke and duchess. On the right hand is a statue of Generosity, and on the left a fine one of Hercules. Above these, on each side of the marble columns, are a statue of Mars with his spear, and of Religion with her cross. The Chateau d'Eau, which supplies the town with water, is an elegant little building. The collegium, which seems to have been a huge building, is in ruins. The town is almost surrounded with a splendid promenade, flanked with fine poplars. Moulins contains also a public library, public baths, and a small theatre. The principal article manufactured here is scissors. The town has very little trade. Population about 14,000. East Long. 3° 20′ 5″, and North Lat. 46° 34′ 4″.

MOUNTAINS. See Mineralogy, in this volume, and Physical Geography.

MOURZOUK, the capital of the kingdom of Fezzan, is situated in 27½° of south latitude, and 15½ of east longitude. It is the great market and place of resort for various caravans from Cairo, Bengasi, Tripoli, Gadames, Twat, and Soudan, and for the smaller troops of African traders. Though Mr. Horneman resided in this place for several months, he has given no description of it as a city. Its inhabitants carry on no manufactures, and produce no other handicrafts but those of smiths and shoemakers. They are remarkable chiefly for their drunkenness and lewdness. For an account of the country and people, see Fezzan.

MOZART, John Chrysostom Wolfgang Theophilus, a celebrated composer, was born at Salzburg, in Bavaria, on the 17th of January, 1756. From the earliest age he testified the strongest predilection for music, which induced his father, who was organist of the prince's chapel, to discontinue the instruction of others, in order to devote himself to his tuition, and that of a sister, about four years older. After learning the harpsichord during a year, the flights of his genius were so rapid, that he exercised his own invention in original compositions at the age of only five, and attempted notation, which could be hardly decyphered. Being carried to Munich, along with his sister, both of them performed before an audience at Bavaria, and also in presence of the Emperor, Francis I. at Vienna, with equal approbation.

In 1763, Mozart publicly performed a conçerto on the violin at Munich; and having exhibited his talents in different towns of Germany, he was carried to Paris, where he played the organ of the king's chapel before the French court. An engraving of him, in which both his father and sister are introduced, was published in this city in 1764, describing him "composer and master of music, aged seven years." Mozart next reached London, where he excited great admiration: And doubts being entertained whether his real age was not disguised under a juvenile appearance, Mr. Barrington obtained a certificate of his birth by means of the Bavarian ambassador. It was proved by experiment, that he actually understood composition as a science; and at a concert given by himself and his sister, all the symphonies performed were his own. Precocious children have appeared in Britain, both before and since that period, as Dubourg and Clegg, performers on the violin, and Kruntzen on the harpsichord, of an earlier date; and in later times, Pinto, Gattie, and Miss Treemearn, who, at eight or nine years old, played a violin concerto in Covent Garden Theatre, in 1817. Mrs. Billington's talents, also, were exhibited at the age of seven, and in her eleventh year she played a concerto composed by herself. Some of these had greater difficulties to execute; but none, except Mozart, was born a musician, whose skill in the science was enlarging gradually until the last hour of his existence. The family returned to Salsburg in 1766.

The two young musicians performed in the presence of the Emperor, Joseph II. at Vienna, in 1768, when Mozart was commanded by that sovereign to compose the music for a comic opera, which was approved, but never brought out. When only twelve years old, however, he composed and directed the performance of a mass for the dedication of a church. He was accustomed at this time, on receiving an air in company, to set parts to it without retiring.

Mozart next visited Italy, where he experienced the most flattering reception; but the Neapolitans insisting that there was some hidden charm in a ring which he wore during his performance, he removed it, to show there was none. He was elected member of the Philharmonic society of Bologna, and received an order of knighthood from the Pope. A mass called the *Miserere* is performed at Rome, in the Sixtine chapel, twice during Passion Week, by choristers only, with an effect which no other band has been able to produce, insomuch that Leopold I. of Austria having obtained a copy from the Pope, he suspected a spurious composition had been imposed on him, and sent an envoy to remonstrate with his Holiness. The musicians being prohibited to give copies of it, Mozart, by an astonishing effort, committed the whole to memory; he wrote it down at home, after the first performance, and on the second occasion carried it in his hat for correction.

Having previously undertaken to compose the music for a serious opera, to be produced at the carnival of Bologna, he wrote Mithridates in his fifteenth year, which was performed on twenty successive nights; and during four or five years, partly occupied in excursions throughout Italy and Germany, he engaged in several works at the desire of illustrious personages. His parents constantly accompanied him in his travels, for he was so completely devoted to his art as to be regardless of all personal interests.

In 1777, Mozart intended to establish himself at Paris, a plan from which he was diverted by his disapprobation of the kind of music which was fashionable in that city.

After returning to Salzburg in 1779, he resolved to fix his future residence in Vienna, where it is affirmed that he became the pupil of Haydn. We are doubtful of the fact, but this master held him in high estimation; and it is known, that a few years later he did not scruple to affirm that he was the greatest composer of the age.

For a number of succeeding years, Mozart did little else than compose music with amazing reputation; he was powerfully promoting that grand revolution which was substituting energy, variety and expression, for the languor and monotony which pervaded the works of most of his predecessors. His operas, symphonies, quartetts, songs, and dances, were all received with unexampled avidity. But the period when he became passionately enamoured of Constantia Weber, a celebrated actress, was not the least brilliant of his compositions, for it is under such impressions that men are most earnest to distinguish themselves. Tenderness is the leading characteristic of his works, and he had now an opportunity of displaying all his science and feeling in an opera, called *Idomeneo*, which, in the year 1781, had been demanded from him by the Elector of Bavaria. Mozart was wont to esteem it the best of his productions, along with *Don Juan*, an opera of another kind. The success of the latter, which was composed for the theatre at Prague, in 1787, was more equivocal. Though the work had been undertaken for a considerable time, Mozart, instead of fulfilling his engagements, had spent the day preceding that for which the performance was announced in hunting, for he was immoderate in the pursuit of pleasure. The general rehearsal had taken place, but the overture was yet to be written. After partaking of some exhilarating beverage, he sat down to finish his task, when, overpowered by fatigue, he soon fell fast asleep. His wife allowed him to repose two hours, and having awakened him at five in the morning, he completed the work, which was heard in the evening. Critics pretend that the parts where the composer's faculties were overcome, are betrayed in the composition; and certainly the first movement contains passages from which earlier musicians would not have earned fame. Don Juan, now better known by the name of Don Giovanni, was not performed in the Opera House, London, until 1817, thirty years after its date. Here, it may be remarked, that Mozart's habits were very irregular. At times he laboured with incredible application, and would instantly commence the subject of an engagement, but he was not equally assiduous in completing it. He generally composed early in the morning; after which he did nothing during the day, unless it might be adding to works in progress; he was also fond of playing late in the evening, and would pass entire nights with the pen in his hand. In consequence of his habits, and the uncertainty of his profits, as also his generous disposition, Mozart's finances became so much deranged, that about this time he proposed to reside in London.

Before the period of which we speak, however, he had composed a comic opera, *The Elopement from the Seraglio*, by command of the emperor Joseph II., and *The Marriage of Figaro*. On the rehearsal of the former, the emperor, who himself had considerable skill in music, said to him, "My dear Mozart, that is too fine for my ears: there are too many notes in it." "I ask your majesty's pardon," replied the composer, not relishing the criticism, "there are just as many notes as there should be." The emperor was embarrassed, and remained silent. Perhaps Mozart afterwards admitted the justice of the remark, for the opera underwent many retrenchments and alterations. The extension of the scale, and multiplication of musical intervals, constitute a leading distinction between the older and modern composers. Both may be carried to infinity; but as that alone can be called music, from which pleasure is immediately derived, the advantage is not obvious of descending so far, that nothing except a confused flutter is sensible to the ear, or of ascending so high, that the powers of vibration seem exhausted in piercing shrillness. Considering, also, that the finest airs are restricted within a very narrow compass, it is evident that the multiplication of the notes in a bar, until there seems a contest between number and space, and the minuteness of their subdivision, are often of very questionable application. When the opera to which we allude was publicly performed, it received the warmest encomiums from the emperor, with whom Mozart was a great favourite, though without participating much of his bounty. He had been appointed chapel-master to his illustrious patron, to which office no salary was attached, but he received 100*l.* a-year as private composer to him. However, he was attached to his person, and on that account declined an offer of being appointed director of the orchestra of Frederic of Prussia, the sovereign who best of all knew how to appreciate merit.

The production of an opera being an incident of notoriety, to which many have an interest in calling the public attention, the date of other compositions is not so readily ascertained. Mozart wrote a number of pieces merely to gratify his friends, which were afterwards surreptitiously obtained by music-sellers for publication. But copyrights on the continent are less valuable than in Britain, where indifferent ballads are remunerated with ten guineas each, and the music for dramas with 1000*l.* or 1200*l.* Mozart received about fifty guineas for the *Magic Flute*, one of his finest works, and the favourite composer of modern times, Rossini, does not reap more than 50*l.* for a whole opera.

The *Magic Flute* was composed in 1792, and was performed an hundred times at Vienna in the course of a year. But Mozart had frequently to contend with distressing opposition to his works, in the jealousies excited against him among those whom his celebrity eclipsed, and to which he himself believed he at last fell a sacrifice. On the first representation of the Marriage of Figaro at Vienna, some of the principal performers endeavoured to diminish the effect of the finest airs; which so much provoked the composer, very irritable, besides, in musical matters, that he loudly complained to the emperor, then present, who threatened the offenders with his displeasure. In fact, the greater works of Mozart can admit of no diminutions. For the performance of Haydn's *Creation*, it has been remarked that "at least twenty-four voices and sixty instruments are required:" and of Mozart's operas it may be said, that not only the orchestra must be full, but the performers excellent, conditions so rarely attainable, that it is not surprising if a manager, exhibiting his theatrical library, exclaimed with a deep sigh, on pointing to the shelves bearing his name, "These have been my ruin." From this defect they have repeatedly failed.

Independent of our inability to trace the progress of Mozart's works, all have been reproduced under such diversified forms, that it is no easy matter to discover either for what instruments, or for how many parts they were designed originally. But the fertility of his genius embraced every different department of the art; and the period when it was most active can be sometimes ascertained. The rapidity of his composition was astonishing, for *La Clemenza di Tito*, an opera demanded by the Bohemians for the coronation of Leopold II, was begun in his carriage, on a journey to Prague, and finished in 18 days. But already Mozart's health was declining; his anxieties became great, and his application immoderate. Totally absorbed by enthusiasm, he neglected repose, and frequently he fainted from the excessive fatigue attending the ardent prosecution of his labours. At length he fell into a habitual melancholy, from which nothing could arouse him, and he was full of terror at his approaching end. The fatal event, however, was accelerated by a circumstance well calculated to make a deep impression on the morbid sensibility of his mind. When plunged in a profound reverie, a stranger of dignified manners was announced, who communicated the wishes of some unknown person of exalted rank, that he should compose a solemn mass for the repose of the soul of one tenderly beloved, whom he had just lost. An air of mystery pervaded the interview: the composer was exhorted to exercise all his genius; and he engaged to finish his work in a month, when the stranger promised to return. He disappeared, and Mozart instantly commenced writing. Day and night were uninterruptedly occupied: but he was consumed by gloomy presages, and at length exclaimed abruptly to his wife, in great agitation, "Certainly I am composing this requiem for myself:—It will serve for my own funeral."

Though his strength continued to fail, his assiduity was unabated; and at length he was obliged to suspend the undertaking. At the appointed time the stranger returned. "I have found it impossible to keep my word," said Mozart: to which the stranger answered, "Give yourself no uneasiness. What longer time do you require?" Mozart replied, "Another month."—The stranger now insisted on doubling the covenanted price, which he had paid down at the outset, and retired. It was in vain that Mozart endeavoured to trace him; which, conjoined with other circumstances, corroborated his belief that he was some supernatural being, sent to announce the close of his mortal career. Nevertheless, his labours were renewed; and the work at last was nearly completed within the stipulated period, when the mysterious stranger again returned; but Mozart was no more. He died on the fifth of December, 1792, aged thirty-five years.

In person Mozart did not exceed the middle size; he was thin and pale, and his health was always delicate. The expression of his countenance, without any thing striking, was exceedingly variable, and rather that of an absent man. His habits were awkward, and his hands had been accustomed so incessantly to the piano, that they seemed incapable of application to any thing requiring address. He was of a mild and affectionate disposition: his mind was not uncultivated, and the number of his works is a sufficient proof of his industry. His opinions of other composers were liberal, and he entertained the highest respect for Haydn in particular. "Believe me, sir," said he to an officious critic, who sought to demonstrate certain errors of that great master, "believe me, sir, were you and I amalgamated together, we should not afford materials for one Haydn." He was not insensible of the beauties of his own compositions; and on the very day of his decease, calling for the *Requiem*, he had some parts of it performed by his bedside. As the stranger who received this fine work could never be discovered, notwithstanding all inquiries, it would have been lost for ever, but for the preservation of the score by the composer's family.

The genius of Mozart in music was sublime. By the number, variety, combination and effect of his works, he ranks in the highest class of modern masters. An air of delicacy and sentiment pervades the whole. Full and harmonious, they are altogether free of that meagreness, and those capricious eccentricities, which betray the sterility of invention too common among musicians. The taste which they exhibit shows that vulgar images were incompatible with his mind; it seems as if he knew that such a deformity is alike pernicious to science and the arts. A vulgar composer is struggling to carry mankind back into the path which they have left far behind them; a polished composer, in outstripping his contemporaries, lays open a beautiful field, which he invites them to enter. Mozart has been most successful in gloomy passages, or those of rising grandeur, from according better with the ordinary train of his feelings. On almost all occasions he is more serious than comic, in endeavouring to pourtray the passions; and his love, it has been remarked, is rather sentimental than sportive. However simple the theme, however intricate its variations, his return is always natural, and the close appropriate. Perhaps the celebrity of Mozart's music partly arises from the skilful management of his closes; for they invariably leave an agreeable impression. No one has surpassed him in the suitable occupation of the parts of his concerted pieces; for, understanding the precise qualities of every different instrument, nothing is appointed to any which is inconsistent with its character.

Notwithstanding the excellence of this composer's works, he is charged with some important defects, though it must be admitted that there are fewer inferiorities than in the same number produced by any other. His vocal performers, it is alleged, are sometimes treated as if they constituted part of the orchestra. In passages and intervals of great difficulty they have to contend against the overpowering effects of the wind instruments, whence his operas have frequently failed even with good companies. Neither can it be denied, that nearly all the subjects of all his symphonies want that interest which characterizes those of Haydn, that they are noisy, thus participating of the grand fracas of instruments, wherein the Germans seem to place their chief delight; and what is more singular, that none of them command the attention of an audience. Undoubtedly his quintetts, quartetts, and piano-forte compositions are very fine; yet they are less interesting to the hearer than to the performer. Their recondite properties are perhaps too slowly unfolded for a transient performance; but, for the same reason, their subsistence should be more permanent, as that which becomes familiar soon loses its charms. In the vocal department, however, Mozart has certainly excelled Haydn. Here he has profited by a precept of that inimitable master, who himself, by a strange inconsistence, appears to have transferred it from the voices to the instruments. "Let the air be good," said Haydn, "and the composition, whatever it is, will assuredly please. It is the soul and essence of music."

In contrasting the merit of composers, their æra is to be taken into account. Handel, though born only 30 years later than Corelli, aimed at effects which the other never conceived, and quite disconcerted him by his novelties. The youth of Haydn was cotemporary with Handel's age. Mozart followed, and both have executed what it is doubtful whether Handel ever contemplated. Descending still later, the works of Beethoven seem to exceed the views, but we shall not say the qualities of all his predecessors. Neither is the structure of the orchestra to be overlooked, for, independent of the combinations of musical phraseology, the subdivision and extension of the scale, it is there that we must also seek much of the varieties of modern music. Every theme being simple in itself, the older composers retained that simplicity; their vocal parts had few accompaniments, but the moderns cultivate the highest embellishments of the voice, while they sometimes forget its right of predominancy amidst contending harmonies. The instruments were few, and of very limited compass, and the essence of the composition was restricted to the hands of the leader. Now they are multiplied, the scale is enlarged beyond all the bounds of emphatic expression, and the finest passages of the music are dispersed every where; thus producing greater variety, which requires greater address. Corelli's pieces, excluding the organ *ad libitum*, have no wind instruments: Handel in general uses them sparingly: but Haydn does not scruple to give the hautbois or bassoon a solo: Mozart frequently calls on the pre-eminence of the flute: Cherubini displays the bass; and, as if all the powers of melody were exhausted, Beethoven finds a wide vacancy for kettle-drums. Perhaps the roundness and fulness so peculiar to some of this author's works, results merely from the more copious use of graver intonation. Composers also, not content with imitative, have attempted descriptive music, as if, from the faint resemblance which may be produced of the roll of distant thunder, it were equally possible to represent the flashing of lightning, or the shock of an earthquake. But no descriptive or imitative music has yet betrayed its original: on the contrary, the composer is chiefly indebted to the pliant imagination of his audience, coupled with pointed verbal explanations. On the whole, we are inclined to rank Mozart next to Haydn.

Like most other great composers, Mozart probably has written too much. Many men mistake fertility for invention; but the real brilliance of original genius is soon exhausted, and on this account it is that, in the vain pursuit of novelty, they wander into inconsistencies, which, although a temporary support, are ultimately fatal to their works. The total number of Mozart's compositions, we have understood, amounts to 115, among which are 12 dramatic operas, 17 symphonies, 6 original quintetts for violins, tenors and violincello, 10 quartetts, and 1 trio for the same instruments, together with 2 duetts for violin and tenor. He wrote many pieces for the piano, and all other instruments; but several changes have been made in the arrangement of his music, both by himself and its editors. One of his piano-forte quartetts was a quintett, and one of his violin quintetts originally adapted for eight wind instruments.

Mozart married Constantia Weber in 1781, by whom he left a son and a daughter. After his decease, his family met with ample protection and support from the inhabitants of Vienna, who were grateful for the pleasure they had derived from his works. His sister abandoned the musical profession on marrying a counsellor of the Prince, bishop of Salzburg. It is said, that his son, following in his footsteps, has composed between 15 and 20 operas, chiefly for the piano-forte, but without gaining equal celebrity. (*c.*)

MULL, one of the western islands of Scotland, is in the county of Argyle, and is the third in point of magnitude. It is of a very irregular form, and so much invaded by arms of the sea, that its circumference is above 300 miles, although its greatest diameter does not exceed 35. It is divided into three parishes, Kilfinichen, Kilninian, and Torosay; of which the following was the population in 1811.

Kilfinichen,	3205
Kilminian,	4064
Torosay,	2114
Total,	9383*

The superficial contents of the island are 420 square miles, or 210,000 Scotch acres.

The parish of Kilfinichen, generally called the parish of Ross, occupies the south-western part of the island, and extends 22 miles in length, and 12 in breadth. It includes the islands of Inchkenneth, Eorsa, and Icolmkill. It is in general barren and mountainous. The shores are bold and rocky, exhibiting in many places basaltic columns; and there are good marble quarries in different parts of the parish. The kelp made annually varies from 70 to 120 tons.

The parish of Kilninian occupies the peninsula in the north-west part of the island, and extends about 12 miles in length, and 12 in breadth. It includes the inhabited isles of Ulva, Gometra, Little Colonsa, and Staffa, and the uninhabited cluster called the Treshinish Isles. The parish is in general hilly; but the arable land on the coast is tolerably good and fertile. This parish manufactures from 170 to 180 tons of kelp annually, at the expense of about 30s. per ton. There are five lakes in the parish, abounding with trout. Salmon are caught at the mouth of several of the rivulets. The town and harbours of Tobermory and Aros are in this parish.

The parish of Torosay, or Pennygown, occupies the south-east side of the island, and stretches along the sound of Mull. It is about 12 miles wide in every direction. Its general aspect is rugged and mountainous. The highest part of it, viz. Benmore, is 3097 feet, as determined barometrically by Dr. Macculloch, while Benychat, the highest hill next to it, is 2294. The parish is excellently adapted for sheep pasture. Castle Dowart, once the residence of the chief of the Macleans, stands on a lofty promontory, overhanging the Sound of Mull, and, till lately, was occupied as barracks for a small party of soldiers from Fort William, stationed here to check the smugglers. The parish contains several birch woods, annually cut for charcoal. There are some red deer in the mountainous parts of it.

The Duke of Argyle is the principal proprietor in Mull, the number of proprietors amounting to about 10. The Duke possesses nearly one half of the island.

The climate of Mull is remarkable for its extreme wetness. It is more subject to rain than any of the western islands, exceeding even in this respect Rum or Sky, which rank next to it. Dr. Macculloch ascribes this to the altitude of its own hills, and to that of the range which extends from Cruachan to Ben Nevis, which assists in precipitating the clouds that arrive from the western ocean. From its being immediately open to the sea, it receives with undiminished energy gales of wind

* Dr. Macculloch, in 1819, estimates the population at ten thousand.

and rain, of which the inhabitants of better climates can scarcely form a conception.

The principal town and harbours in Mull, are Tobermory and Aros. Tobermory (St. Mary's Well) was begun in 1789, under the auspices of the Society for the Encouragement of Manufactories and Fisheries. A custom-house and post-office were built in 1791, and many good houses of stone and lime, and covered with slate, have been since erected. It has of late increased in population, and now contains about 600 inhabitants. It has a fine bay and harbour, sheltered from the ocean by the Isle of Calve. It had, in 1810, 11 registered vessels, manned by 29 men, and amounting to 278 tons burden; and there are, besides, 28 open boats, with three men each, which are commonly employed in the fishery. The village has therefore 113 seamen. In 1808, the number of vessels which entered inwards was 58, and those which cleared out 70. There is also a harbour at Aros, and near it a picturesque old castle, which is said to have belonged to the Lord of the Isles. The castle of Moy, situated in Loch Buy, is another of the antiquities of Mull. It is very entire, and forms a fine contrast with the modern excellent mansion-house which stands near it. See M'Donald's *Agricultural Survey of the Hebrides*, p. 669. Edin. 1811; Smith's *Agricultural Report of Argyleshire*, Lond. 1813; and Dr. Macculloch's *Description of the Western Islands*, vol. i. p. 530, 537, and vol. iii. p. 73. Edin. 1819.

MULTIPLIER. See ELECTRICITY.

MUMMY. See EMBALMING.

MUNDEN. See MINDEN.

MUNICH, the capital of the kingdom of Bavaria, is situated in a plain on the west bank of the Iser. It is surrounded with a rampart, which incloses three-fourths of the houses, the other one-fourth constituting the suburbs. Munich is divided into four quarters by means of two spacious streets, at right angles to one another, the place of intersection forming the principal square. The streets are in general broad, and the houses neat and well built, though high. The principal public building is the palace, which, though plain in its exterior, is within splendid and magnificent. It contains a grand saloon, called the White Horses; the grand imperial hall, which is reckoned the finest in Germany; the cabinet, adorned with 130 miniatures, each of which is valued at 200 old Louis; the bed of Charles VII. the embroidery of which, in gold, silver, and pearls, weighs 24 quintals; a tapestry, representing the actions of Otho of Wittlesbach; the great marble staircase; the gallery of pictures; the treasury, containing a large collection of diamonds, rubies, emeralds, &c.; the royal chapel, with its valuable deposits, such as a virgin of gold, weighing 22 lbs., a superb picture of Michael Angelo, and the small altar which Mary, Queen of Scots used in prison; a fine organ, the famous palatine pearl, and the model of Trajan's column, which cost 10,000 ducats, the ground being of lapis lazuli, and the bas relief in bronze. It was executed in 1780 by Livadier, and the bas reliefs by Bartolom.

The principal church of Munich is that of Notre Dame, which contains the monument of the Emperor Louis IV. besides thirty altars, and paintings of great value. The church of the Theatins, built on the model of the Vatican, contains a fine painting of the plague at Naples, by Sandrat. The church of the Augustins has a fine painting by Tintoret, which was cut in two in order to get room to snuff the candles. The other principal churches are, that of the ci-devant Jesuits, now belonging to the Knights of Malta; the church of St. Peter, adorned with fine paintings: that of the Knights of Malta, containing a treasure worth two millions of florins; and that of the English religious, who instruct young girls gratis, not only in religion, but in objects of useful industry. Munich contains, altogether, twenty-two churches. The other public buildings are, the old electoral palace; the palace of Prince Eugene Beauharnois; the Jesuits' college, containing several saloons, in one of which the academy of sciences holds its sittings, while another is occupied with physical and mechanical instruments and models, and objects of natural history; the convent of the Franciscans, which contains a fine copy of the last judgment, by Michael Angelo; the land-haus, where the states meet; the council house; the arsenal; the new opera house; the barracks; the mint; the hospital of St. Esprit; the great military garden.

The principal literary and useful establishments are, the academy of sciences, established in 1759; the school of design; the military school; the lyceum; the gymnasium; the seminary for training teachers; the observatory; and the veterinary and surgical schools; the house of industry, and the house of education, both of which were established by Count Rumford; four orphan houses; a lock-hospital, and a house of correction. The principal libraries are those of the king, the Jesuits, and the academy of sciences. The royal library contains more than 100,000 volumes, and possesses a great number of editions of 1400, and some valuable MSS. The first edition of Ptolemy, with maps, is one of the rarities in this library.

Munich carries on very considerable trade in grain, wood, salt and iron. Its principal manufactures are, the royal one of tapestry, one of silk ribbons, gold and silver lace, cotton stockings, piano-fortes, playing-cards, tobacco, beer, which is made to the annual value of a million of florins, porcelain made at Nymphenberg, and brought to the warehouse at Munich.

The environs of Munich are beautiful and agreeable. The king has three royal residences, viz. at Nymphenberg, Schlosheim, and Furstenried. At Nymphenberg, about 1½ miles from Munich, are large gardens and water-works, but the palace is a tasteless mass of buildings, built on the plan of Versailles. The palace of Schlosheim, 12 miles from Munich, is a magnificent building, and contains 300 apartments. The gallery of paintings, for which it was once famous, were removed about 40 years since to Munich, and have been replaced by others. The population of Munich is estimated at 48,000. East Long. 11° 34′ 30″, and North Lat. 48° 8′ 20″. See Kuttner's *Travels*, Lett. xxvi.; Reichard's *Guide des Voyageurs en Europe*, tom. ii. p. 118; and *Abrégé de tout ce qu'il y a de remarkable à voir à Munich*, 1790. Par. L'Abbé Bermiller.

MUNSTER, a town of Prussia, and principal place of a government of the same name, is situated in a fertile and agreeable plain on the river Aa, about six miles from the Ems. The town is tolerably built. The houses in the chief streets have colonnades, and are generally lofty and irregular, with painted roofs. Munster possesses eleven churches, the principal of which are the cathedral, and the church of St. Lambert. In the former is the remarkable chapel of Bernard de Galen, and several ancient monuments; and at the top of the tower of St. Lambert's are still seen the three iron cages in which were suspended John of Leyden, the king of the Anabaptists, and his two chief abettors. The episcopal palace is a neat building, with extensive and beautiful gardens. Munster has three schools for the education of youth, who pursue their maturer studies at the university of Bonn, established in 1818. A small trade is carried on in linen, woollen, wine and grain, and there are some small manufactories of coarse linen. The ramparts are flanked with trees, and form a beautiful promenade. The population was formerly 25,000, but it is now stated at 13,000. East Long. 7° 36′ 21″, and North Lat. 51° 58′ 10″.

MURCIA, a province in Spain, on the shores of the Mediterranean, extends above 30 leagues from north-west to south-east, and 20 from the south-west to the north-east. It is a dry hilly country, almost covered with mountains, which are chiefly branches of the Montes Orospedani. The most remarkable of these, in extent and elevation, is that of Carascoy, to the south-east, a continuation of the Sierra de Cazoila, which stretches also into Jaen on the south, and into Granada on the north. None of these hilly regions are cultivated, though the soil is well suited for vines and olive trees. The mountains of the province have the appearance of containing many valuable mineral productions; and there are traces of lead, copper, alum, sulphur, and silver mines. Feathered alum, or false asbestos, is found near the village of Almanzarron; rock-crystals on two mountains near Carthagena; a large salt pit near Villena; and various kinds of marble, particularly on a lofty ridge towards the frontiers of Granada on the north-east. There are hot mineral springs in several places, which are used in paralytic and rheumatic disorders, especially one at Archena, four miles from Murcia, which was much celebrated under the Arabs, and where ruins of Roman edifices have been discovered.

There are only two rivers in the province, the Segura and the Guadalentin; and the last of these is little more than a brook. The climate is remarkably temperate, except in the neighbourhood of Murcia and Carthagena, where the heat is almost insupportable in summer. The sky is uncommonly serene and clear; and rain falls very rarely in any part of the province.

The soil is generally dry, but a little rain has great efficacy in the more parched plains. In the watered plains, along the banks of the Segura, it is uncommonly fertile; but, except a few olives and mulberries, there is nothing but corn raised upon them. The soil, in general, requires little cultivation, and wherever irrigation can be practised, yields the most abundant returns; but the inhabitants have no skill in agriculture, and are too indolent to avail themselves of the advantages within their reach. Except around the principal towns, where the grape is cultivated, and wine made, little else is raised in the province but corn, chiefly wheat, rye, and barley. A considerable quantity of Spart, or Spanish broom, is still cultivated near Carthagena, for making shoes; but in the time of the Romans, the country was so covered with it, that Pliny says it furnished the common people with materials for making bedding, clothes, shoes, and fire. Hemp is cultivated in the watered plains: saffron is raised in some places; and olive oil, though of an inferior quality, is made in considerable quantity. But next to wheat, the most valuable produce of the province is silk, for which the white mulberry trees are every where cultivated, and of which about the value of 260,000*l.* is annually prepared. The whole produce of the province is estimated at 1,436,875*l.* There are few manufactures in the province; and even the greater part of the raw silk prepared in the country is sold to the neighbouring provinces, while manufactured silk is imported from other places. It is only in the town of Murcia that a manufactory of silk and ribbons is carried on to any extent. Soap is made at Villena and Murcia; hardware at Albacete; brandy at Sar and Villena; salt-petre and gunpowder at Murcia; and spart is made in private houses into shoes, mats, baskets, cordage, and package coverings.

There is little inland commerce in the province, as the roads are generally in a very bad state; and there are few commodities to support a foreign trade. The exports are cutlery, ribbons, worked spart, wine, silk, grain, kali, saffron, to the amount of 493,038*l.* annually; and the imports are fruits, beef and mutton, wines, spices, linens, cloths, silk stuffs, hardware, and a few articles of luxury. But the balance is in favour of the exports, which brings some wealth into the country every year.

There are no inns in the province, except in the towns of Murcia and Carthagena; and the posades are very bad. Coaches, calashes, and volantes, are used in travelling; and there are various little carts and waggons, drawn by mules or oxen; but asses are principally used in carrying burdens. No attention is paid to the arts and sciences in the province. There are no artists, nor even a tolerable workman in the whole of it. Except at Carthagena, where the institutions for education are confined to the pupils for the royal navy, there are only a few miserable schools kept by monks. There are two public libraries in the town of Murcia; but few persons make any use of them. The principal towns of this province are, Murcia, Carthagena, Lorca, Jumilla, Albacete, Almanza. The country is thinly inhabited, except in the more fertile plains, where the villages are closely crowded. The population is not above one-half of what it might contain; and in 1788, did not exceed 338,000.

The natives of this province are remarkable for their apathy and indolence. They seldom remove from their native spot, to enter the army, the navy, or the universities. The more wealthy individuals spend their whole time in eating, sleeping, or smoking cigars. The shopkeepers, the mechanics, and even the peasantry, are constantly retiring to their meals, or their repose, and do not employ a quarter of the day at their work. Even the domestic servants, in the summer season, when it is easy to procure subsistence, leave their places, and refuse to labour when they can live without it. They are indifferent even about walking abroad for recreation; and either spend their days within doors, or sit down if they come into the open air. They seldom visit one another's houses, nor take any part in amusements, nor bestow any attention on dress and furniture. It is only in Carthagena that the inhabitants show any activity, affability, or enjoyment; but these are chiefly foreigners, collected in the place for the purposes of trade. See Laborde's *View of Spain*, vol. ii. (*q.*)

MURCIA, the capital of the above mentioned province, is situated on a level spot in a large and beautiful valley, watered by the Segura, and ornamented by extensive plantations of mulberry trees. It does not appear to have existed in the time of the Carthaginians or Romans; and is first mentioned about the end of the Gothic dynasty in Spain. It is frequently noticed in history after the beginning of the eighth century, as alternately subject to the Caliphs of Cordova and the kingdom of Granada; and it was not till 1265 that it was taken possession of by Alphonso X. King of Castile.

The most ancient families in the place are of French origin; and still bear names which indicate their descent from that nation. Murcia was formerly a fortified city; and some remains of its walls and towers are still to be seen. The streets are very narrow, irregular, winding, and badly paved. The houses are ill built, and very few of them are worthy of notice. Many of them are of ancient architecture, and loaded with ornaments of sculpture, in a bad taste, and of poor execution. There are no public edifices, except the churches; some of which have a good appearance, and the cathedral particularly, though ill proportioned, and awkwardly designed, exhibits many architectural ornaments, and contains a number of paintings. There are several promenades, and a botanic garden, capable of much improvement; but the citizens seldom frequent any of these places of exercise and recreation.

There are manufactories of salt-petre and gunpowder in the town, on the king's account; and others of earthen-ware, silk twist, silk stuffs, spart, and ribbons; and the principal commerce of the place consists in exporting the two last mentioned articles to Madrid.

It is the see of a bishop, whose diocese includes almost the whole present kingdom of Murcia, and who enjoys a revenue equal to 22,916*l.* 14*s.* 4*d.* The town contains eleven parishes, and a population of 60,000 inhabitants; which includes, however, the inhabitants of the adjoining plain, who may amount to one-third of the whole number.

Many noble Spanish families reside in the place; but the citizens in general spend their lives in sloth and indifference, and are totally ignorant of every thing beyond the boundaries of their city. They are of a yellow, sun burnt, and even livid complexion; a gloomy and choleric temperament. Their indolent habits, bad food, and excessive use of iced-water, renders them subject to ill health. The universal remedy employed by them is bleeding in the hand; and few of them are known, who do not lose blood ten or twelve time every year. See Laborde's *view of Spain*, vol. ii. (*q*)

MURIATIC ACID. See Chemistry.

MUSCA. See Entomology.

MUSCAT, Mascat, or Meschet, a city of Arabia Felix, situated at the entrance of the Persian Gulf, under the tropic of Cancer, and in 57° 26′ of east longitude. It is the most considerable town, though not the capital of the province of Omon; and the Imaum, or prince of the country, is usually styled the Imaum of Muscat. His dominions extend about 300 miles along the Persian Gulf, and nearly as far inland, till they touch the territories of the prince of Yemen. The town of Muscat is built on a level spot, between two rocky hills, on which are erected a number of well placed batteries, capable of making a formidable defence against any attack from the sea. The harbour, which resembles the figure of a horse-shoe, with the entrance at the south-east point, is remarkably well sheltered from the most prevailing winds, and so capacious, that several hundreds of ships might ride in it with perfect safety and convenience.

The Portuguese, after their expulsion from Ormus, took possession of this town in 1508; and besides strengthening its fortifications, adorned it with many public buildings. During a century and a half, they carried on a profitable trade with the Arabs for gums, drugs, hides, bees-wax, cattle, sheep, &c. in exchange for which they supplied them with tobacco, coffee, India and European goods. But about the middle of the seventeenth century, they were expelled by the Arabs; and all their attempts to regain possession of the place only served to improve the military and maritime power of the natives. The Muscateers carry on frequent hostilities with the Persians; but, at the very time when they would capture all ships of war and other vessels at sea, bound to other ports, they allow them free permission to enter the port of Muscat, or any of its dependencies, to purchase goods for ready money, and to pass safely homeward with their cargoes. So much of the patriarchal form of government is said to prevail in this city, that the Imaum is obliged to obey a summons before the Cadi, at the instance of any of his subjects, who might account himself aggrieved. The inhabitants are described as the most liberal minded of all Mahomedans, polite in their conduct to strangers, upright in their mercantile transactions, temperate in their mode of living, chaste in their manners, and rarely guilty of crimes requiring cognizance of the laws.

The climate of Muscat is extremely hot and dry. The rainy season extends from November to February; but heavy dews fall throughout the whole year, and supply the moisture requisite for vegetation. The mountains immediately behind the city are stony and barren; but the adjoining valleys are extremely fertile, and produce a variety of excellent fruits and grains. Wheat and barley are sown in December, and reaped in March. Oranges and lemons (supposed to have been introduced by the Portuguese,) grapes, apricots, and peaches, are abundant. The mango is produced in the greatest perfection; and their stones used to be carried to India for seed, as a better species than any to be found in that country. But the fruit most extensively cultivated, and for which the district is most celebrated, is the date, of which large cargoes are regularly exported. There is a great variety of excellent roots and pot-herbs; and sheep, cattle, and especially fish, may be purchased at a very cheap rate. Fresh water is conveyed to the shipping in a very peculiar manner. As the road from the spring is full of sharp rocks, and does not admit of casks being rolled along it, the water is carried down in skins, and emptied into boats constructed for the purpose; but these are sometimes apt to ship so much sea-water, as to spoil the whole cargo, or at least to render it unpleasantly brackish.

This town carries on a very extensive trade, and sends a number of large ships to the ports of the Red Sea, and on the coast of Malabar. The goods brought from these places are again transferred to trading vessels from both sides of the Persian Gulf, and from the coast of Caramania as far as the river Indus. The inhabitants also maintain a large inland trade, not only with the subjects of their own prince, but with numerous tribes of independent Arabs, to whom they send India piece-goods, pepper, ginger, rice, tobacco, coffee, sugar, with other kinds of India produce, beside English cutlery, cloth, toys, &c.; from whom they receive in return, gums, drugs, ostrich-feathers, hides, sheep and lamb-skins, honey, bees-wax, live cattle and sheep. The town is sometimes so full of goods, that the warehouses are not able to contain them; and they are said to remain night and day piled upon the streets, without any protection, and yet without any danger of being pilfered. Muscat has recently become a mart for importing slaves from Africa, who are thence shipped to Bushire and Bussorah. (*q.*)

GENERAL EXPLANATION

OF THE

PLATES BELONGING TO VOLUME THIRTEENTH

OF THE

AMERICAN EDITION

OF THE

NEW EDINBURGH ENCYCLOPÆDIA.

PLATES CCCLXXII, CCCLXXIII.

Contain Diagrams illustrative of the article Mensuration.

PLATE CCCLXXIV.

Fig. 1. A Thermometer with the Centigrade and Fahrenheit's Scale.
Figs. 2, 3. Represent the Self-registering Thermometer.
Fig. 4. Mr. Adie's Sympiesometer.
Figs. 5, 6. The Self-registering Hygrometer.
Fig. 7. A Pluvimeter, or Rain Gauge.
Fig. 8. Mr. Anderson's New Atmometer.
Fig. 9. Diagram for explaining the Theory of Rain.
Fig. 10. Diagram for representing Varieties of Temperature.

PLATE CCCLXXV.

Fig. 1. Cassini's Reticulum, or Micrometer.
Fig. 2. Dr. Bradley's improved Reticulum.
Fig. 3. Cavallo's Mother of Pearl Micrometer.
Figs. 4, 5. Dr. Brewster's Circular Mother of Pearl Micrometer.
Fig. 6. Prony's Nonius Screw for Micrometers.
Figs. 7, 8, 9, 10, 11. Diagrams, &c. for explaining and describing Dr. Brewster's Optical Wire Micrometer.
Fig. 12. Dr. Brewster's Eye-piece Micrometer for Refracting Telescopes.
Fig. 13. Dr. Brewster's Eye-piece Micrometer for Reflecting Telescopes.
Fig. 14. Diagram for explaining the principle of Divided Object Glass Micrometers.
Figs. 15, 16, 17, 18. Method of measuring Angular Spaces in the heavens by it.
Figs. 19, 20, 21. Dr. Maskelyne's Prismatic Micrometer.
Fig. 22. Ramsden's Catoptric Micrometer.
Figs. 23, 24. Ramsden's Dioptric Micrometer.

PLATE CCCLXXVI.

Figs. 1, 2, 3. Dr. Brewster's Divided Object Glass Micrometer.
Figs. 4, 5, 6, 7. Sir W. Herschel's Position Micrometer.
Figs. 9, 10, 11, 12, 13. Dr. Brewster's Position Micrometer.
Figs. 14, 15, 16, 17, 18. Sir W. Herschel's Lamp or Lucid Disc Micrometer.
Figs. 19, 20. Rochon's Doubly Refracting Micrometer.
Figs. 21, 22, 23. Dr. Wollaston's Single Lens Micrometer.
Fig. 24. Dr. Brewster's Micrometrical Comparer.
Fig. 25. Microscopical Micrometer by Double Refraction.

PLATE CCCLXXVII.

Figs. 1, 2, 3. Mr. Stephen Gray's Water Microscope.
Fig. 4. Mr. Gray's Fluid Reflecting Microscope.
Figs. 5, 6. Dr. Brewster's New Single Microscope.
Fig. 7. Dr. Wollaston's Periscopic Microscope.
Figs. 8, 9, 10, 11. Dr. Brewster's Improvements on the Periscopic Microscope.
Fig. 12. Common Flower and Insect Microscope.
Fig. 13. Microscope for Opaque Objects.
Fig. 14. Withering's Botanical Microscope.

Fig. 15. Pocket, Botanical, and Universal Microscope.
Fig. 16. Lyonet's Anatomical Microscope.
Fig. 17. Wilson's Pocket Microscope.
Fig. 18. Dr. Smith's Compound Microscope.

PLATE CCCLXXVIII.

Fig. 19. Cuff's Double Constructed Microscope.
Fig. 20. Universal Compound Microscope.
Fig. 21. Amici's Reflecting Microscope.
Fig. 22. Dr. Brewster's Reflecting Microscope.
Fig. 23. Mr. Waddel's Compound Microscope.

PLATE CCCLXXIX.

Fig. 24. Method of viewing and illuminating Microscopic Objects.
Fig. 25. Æpinus's Method of illuminating Microscopic Objects.
Figs. 26—33. Represents Martin's Solar Microscope, and the apparatus which accompanies it.
Fig. 34. Improvement on the Solar Microscope.
Figs. 35, 36, 37, 38. Represent Adam's Lucernal Microscope.
Fig. 39. Shows a new Method of illuminating objects in the Solar and Lucernal Microscopes.

PLATE CCCLXXX.

Fig. 1. Is the Lobster Insect, which is found on the Legs of a Fly, and also occurs in Books and Paper, and in Plants.
Fig. 2. Is an Insect denominated the *Thrips Physapus*, which is found on the Dandelion, and other Plants and Flowers. The body is black, and the wings white.
Fig. 3. Represents the *Cimex Striatus*, a beautiful Insect, with its colours very bright, and elegantly arranged. It is found in June on the elm-tree.
Fig. 4. Represents the *Chrysomela Asparagi*, which is found in June on the Asparagus, after it has run to seed.
Fig. 5. Is the *Meloe Monoceros*, found on umbelliferous Plants.
Fig. 6. Represents a Scale from the Sole Fish.
Fig. 7. Shows a Section of a Weed called the Fat Hen, which grows among rubbish.
Fig. 8. Is the Section of a Reed from Portugal.
Fig. 9. Represents a Section of the Bamboo.
Fig. 10. Is a Section of the Hazel.
Figs. 11, 12. Show the Eggs of Moths and Butterflies, particularly the *Phalæna Neustria.*

PLATE CCCLXXXI.

Fig. 1. Represents a Battalion forming Front to the Rear, by a Counter-march of the whole.
Fig. 2. Forming Front to the Rear by a Counter-march of Platoons.
Fig. 3. A Battalion forming Front to the Rear by wheeling about.
Fig. 4. One half faced to the Right-about, previous to Wheeling.
Fig. 5. Forming Front to the Flank, by facing to the Right or Left, and marching up.
Fig. 6. The same, by Deploying.
Fig. 7. The same, by a single quarter Wheel.
Fig. 8. The same, by an eighth Wheel, by Companies, the Flank Company only making an entire Wheel.
Fig. 9. The same, by wheeling round the Centre.
Figs. 10, 11. Forming from Line into Columns.
Fig. 12. Forming, or Deploying, from the Centre.
Figs. 13, 14. A Battalion in Column marching off to the Right and to the Left.
Fig. 15. Marching forwards in Columns.
Fig. 16. Marching to the Rear in Columns.

PLATE CCCLXXXII.

Fig. 17. A Counter-march by Columns.
Fig. 18. Columns breaking off on a narrow road, or defile, without halting.
Fig. 19. The Oblique March by Columns.
Fig. 20. Close Columns forming Front.
Fig. 21. Deploying from the Centre.
Fig. 22. The Movements reversed, the last Division forming the Head.
Fig. 23. Forming Front to the Rear by counter-marching and deploying.
Figs. 24, 25. Close Columns forming Front to the Flank.
Figs. 26, 27, 28. Columns formed by wheeling, placed in order of Battle to the Front.

PLATE CCCLXXXIII.

Figs. 29, 30, 31, 32, 33, 34, 35, 36. Columns forming Front to the Rear.
Fig. 37. Columns deploying close to a Defile.
Fig. 38. Passing Obstacles, and forming Line.
Fig. 39. The Oblique Order in Line.
Fig. 40. The Oblique Order by *Echellons.*
Fig. 41. An Army, in four Columns of March, forming Line.
Fig. 42. An Army attacked on its Flank, changing the direction of its Columns, and gaining the Flank of the Enemy.

PLATE CCCLXXXIV.

Represents the order of Battle at Kollin, between the Austrians and Prussians.

PLATE CCCLXXXV.

Represents the order of Battle at Rossbach, between the Austrians and Prussians.

PLATE CCCLXXXVI.

Represents the order of Battle at Leuthen, between the Austrians and Prussians.

PLATE CCCLXXXVII.

Fig. 1. Represents the order of March and Manœuvres at the Battle of Kollin.
Fig. 2. Represents the order of March at the Battle of Rossbach.
Fig. 3. Represents the order of March and Manœuvres at the Battle of Leuthen.

PLATE CCCLXXXVIII.

Fig. 1. Represents the way in which Strata of Coal meet the Alluvial Cover.
Figs. 2, 3, 4, 5, 6. Represent the Shapes of Coal Fields.
Fig. 7. Shows the Horizontal Section of a Coal Field intersected with Green-stone Dikes.
Figs. 8, 9. Represent Slips in a Coal Field.
Figs. 10, 12. Show the effects produced by Dikes.
Fig. 11. Shows the effects produced by Slips.

PLATE CCCLXXXIX.

Fig. 1. Explains the general Law respecting Dikes and Slips.
Fig. 2. Shows the effect of Hitches or Slips upon Strata of Coal.
Figs. 3, 4. Vertical and Horizontal Section of a Trouble, called a *Nip*.
Fig. 5. View of a Trouble called a Pot Bottom.
Fig. 6. Horizontal Section or Plan of a Coal Field as found immediately under the Alluvial Cover.
Fig. 7. Vertical Section of ditto.
Fig. 8. Shows the effect of a great Slip.
Fig. 9. Is the view of a Coal Field Basin.

PLATE CCCXC.

Fig. 1. Represents various Tools used in boring for Coal.
Figs. 2, 3, 4, 5. Explain the method of conducting a Series of Bores in exploring the Strata for Coal.
Fig. 6. Shows the method of ascertaining Edge Coals.
Fig. 7. A Coal Field where the Fitting is made by a Day Level.
Fig. 8. Represents a quicksand in a Day Level.
Figs. 9, 10, 11. Show the forms of Pits.
Fig. 12. A Bed of Quicksand resting on a Bed of Impervious Clay.
Fig. 13. Iron Gland for fixing Pumps in a Pit.
Fig. 14. Method of keeping back Feeders of Water.
Fig. 15. Represents a Pit widened for Plank Tubbing, or Cribbing.
Fig. 16. Method of wedging a Cutter in the Strata.

PLATE CCCXCI.

Fig. 1. Represents the method of Lowering the Pumps.
Fig. 2. Method of Tubbing and Cribbing.
Fig. 3. See p. 370 and 390.
Fig. 4. See p. 371.
Figs. 5, 6. See p. 372.
Figs. 8, 9. See p. 372.
Figs. 10, 11, 12. See p. 375.
Fig. 13. Shows a simple Mode of Working Coal.
Fig. 14. Shows one of the Shropshire Methods of working Coal.
Fig. 15. See p. 375.

PLATE CCCXCII.

Fig. 1. Represents Mr. Buddle's New System of Pannel working.
Fig. 2. Is one of the Shropshire Methods of working Coal.
Fig. 3. Is a Modification of the Shropshire Method.
Fig. 4. See p. 380.
Fig. 5. See p. 378.

PLATE CCCXCIII.

Fig. 1. Method of working the Shropshire Thick Coal.
Fig. 2. Method of working the Johnstone Thick Coal.
Fig. 3. Method of Working Edge Coals.
Fig. 4 Shafts or Limbers for Horses.
Fig. 6. Position of the Carbonic Acid Gas in Coal Mines.
Fig. 6 to 15. The various Methods of Ventilating Coal Mines.
Fig. 16. Position of the Inflammable Air in Coal Mines.

PLATE CCCXCIV.

Fig. 1. Represents Mr. John Taylor's Hydraulic Airpump.
Fig. 2. Shows Spedding's improved System of Ventilation.
Figs. 3 to 8. Shew the Methods of working Under-dip Coals.
Figs. 9, 10. Represent Dams for keeping back Water in Coal Mines.

PLATES CCCXCV, CCCXCVI.

Contain various Diagrams illustrative of the Principles of *Geology* and *Mineralogy*.

PLATE CCCXCVII.

Fig. 1. Represents a Side Elevation of Mr. Barton's Machine, as used at the Mint, for equalizing the thickness of Metal Plates.
Fig. 2. Is a Horizontal Plan of the same.
Figs. 3—6. Represent several of the Parts separately on a large Scale.

PLATE CCCXCVIII.

Fig. 1. Ocythöe cranchii.
Fig. 2. Two of the Corneous Rings of the Suckers of Loligo sagittata.
Fig. 3. Mandibles of ditto: a, the under one; b, the upper one.
Fig. 4. Pneumodermon peronii.

Fig. 5. Testacella haliotoidea.
Fig. 6. Onchidium typha.
Fig. 7. Doris marginata.
Fig. 8. Thethys fimbria.
Fig. 9. Phyllidia ocellata, upper side.
Fig. 10. Phyllidia trilineata, under side.
Fig. 11. Pleurobranchus membranaceus.

PLATE CCCXCIX.

Fig. 12. Bulla hydatis.
Fig. 13. Valvata cristata, magnified.
Fig. 14. Buccinum undatum, without the shell.
Fig. 15. Hyliotis tuberculata.
Fig. 16. Modiolus vulgaris.
Fig. 17. Synoicum turgens.
Fig. 18. Lingula unguis.
Fig. 19. Tubicinella balænarum.
Fig. 20. Coronula balænaris.

PLATE CCCC.

Is a Map of the Moon's Surface, from a drawing made by Dr. Brewster.

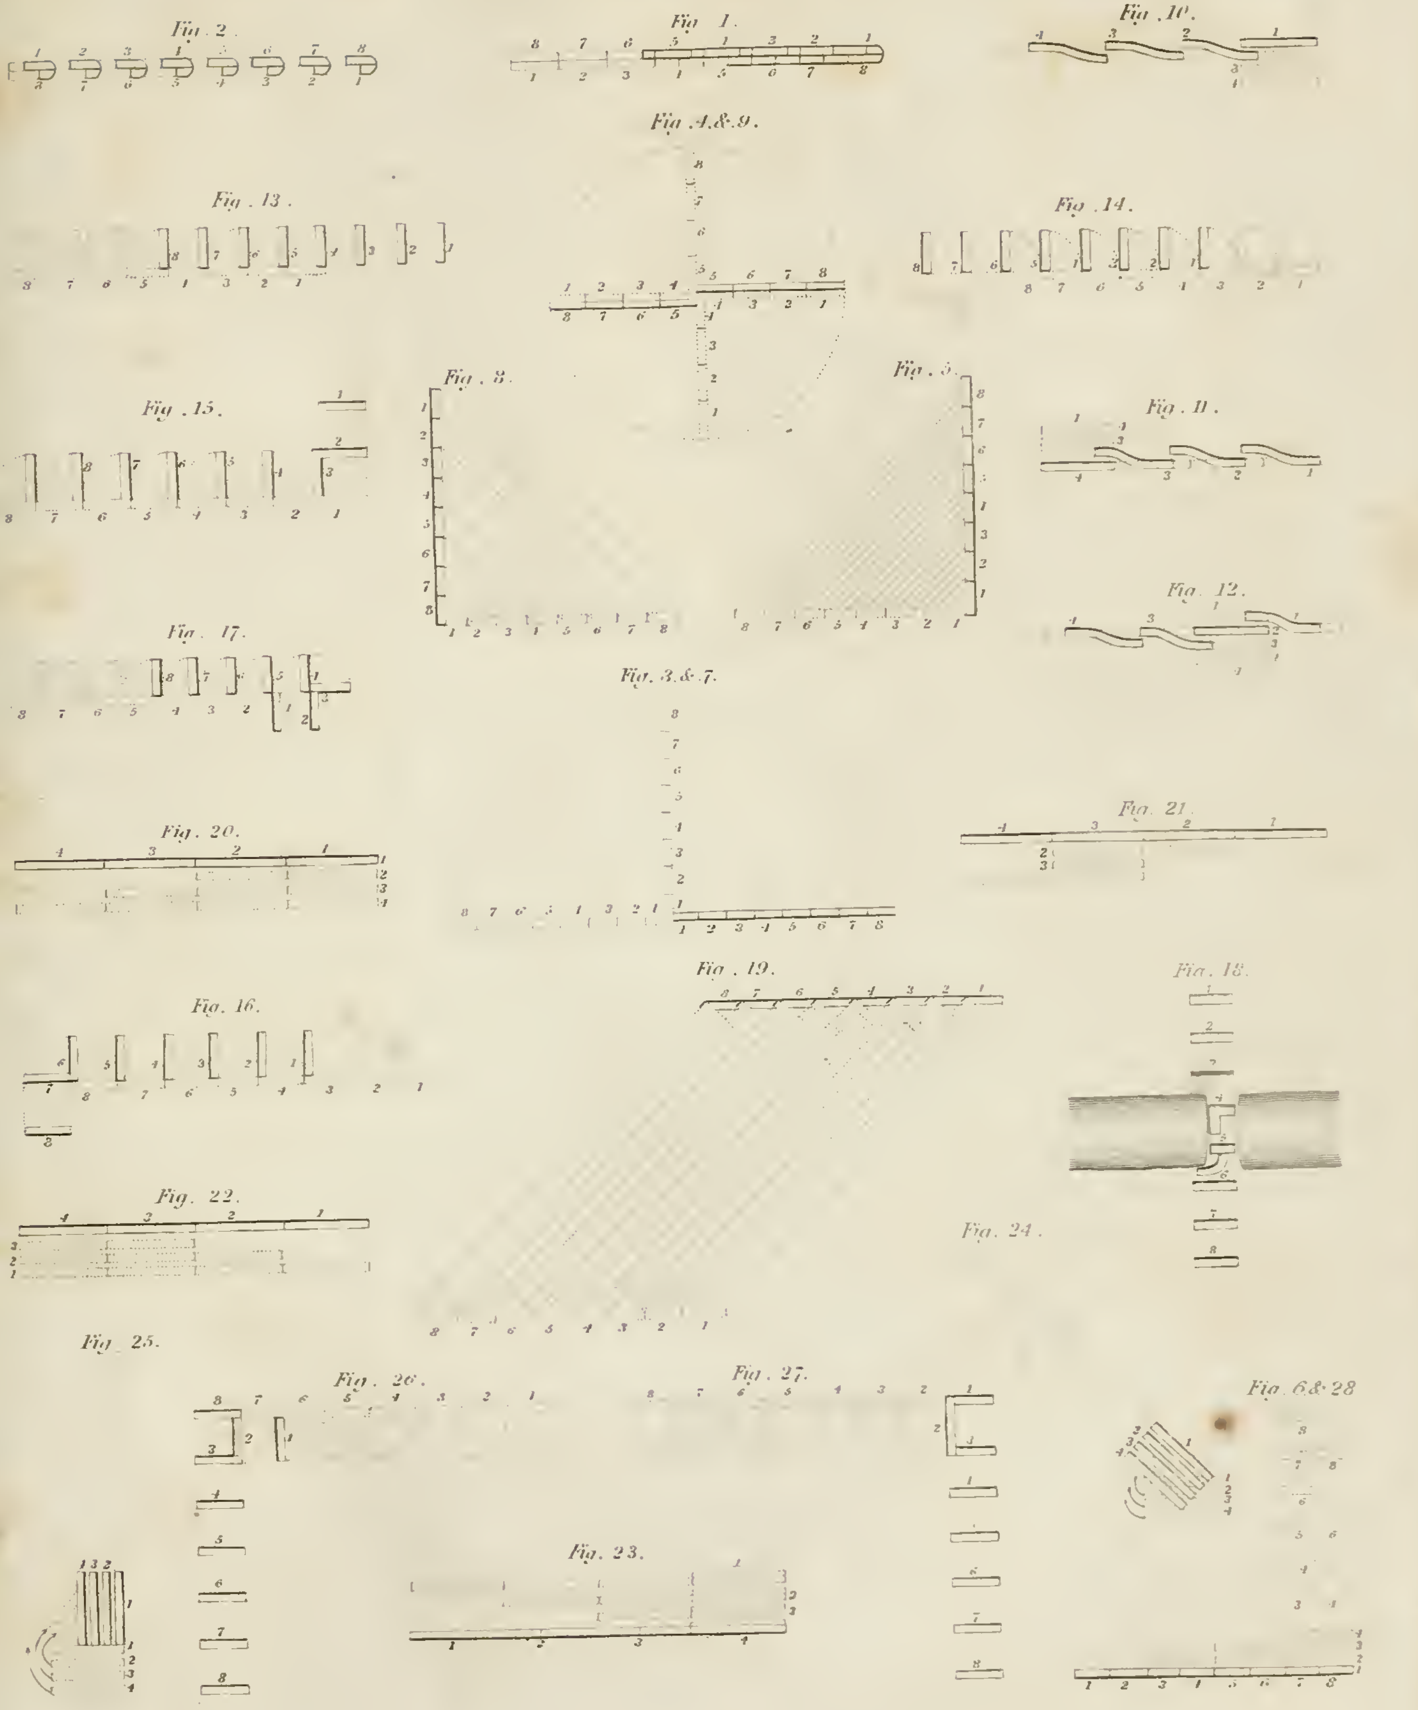
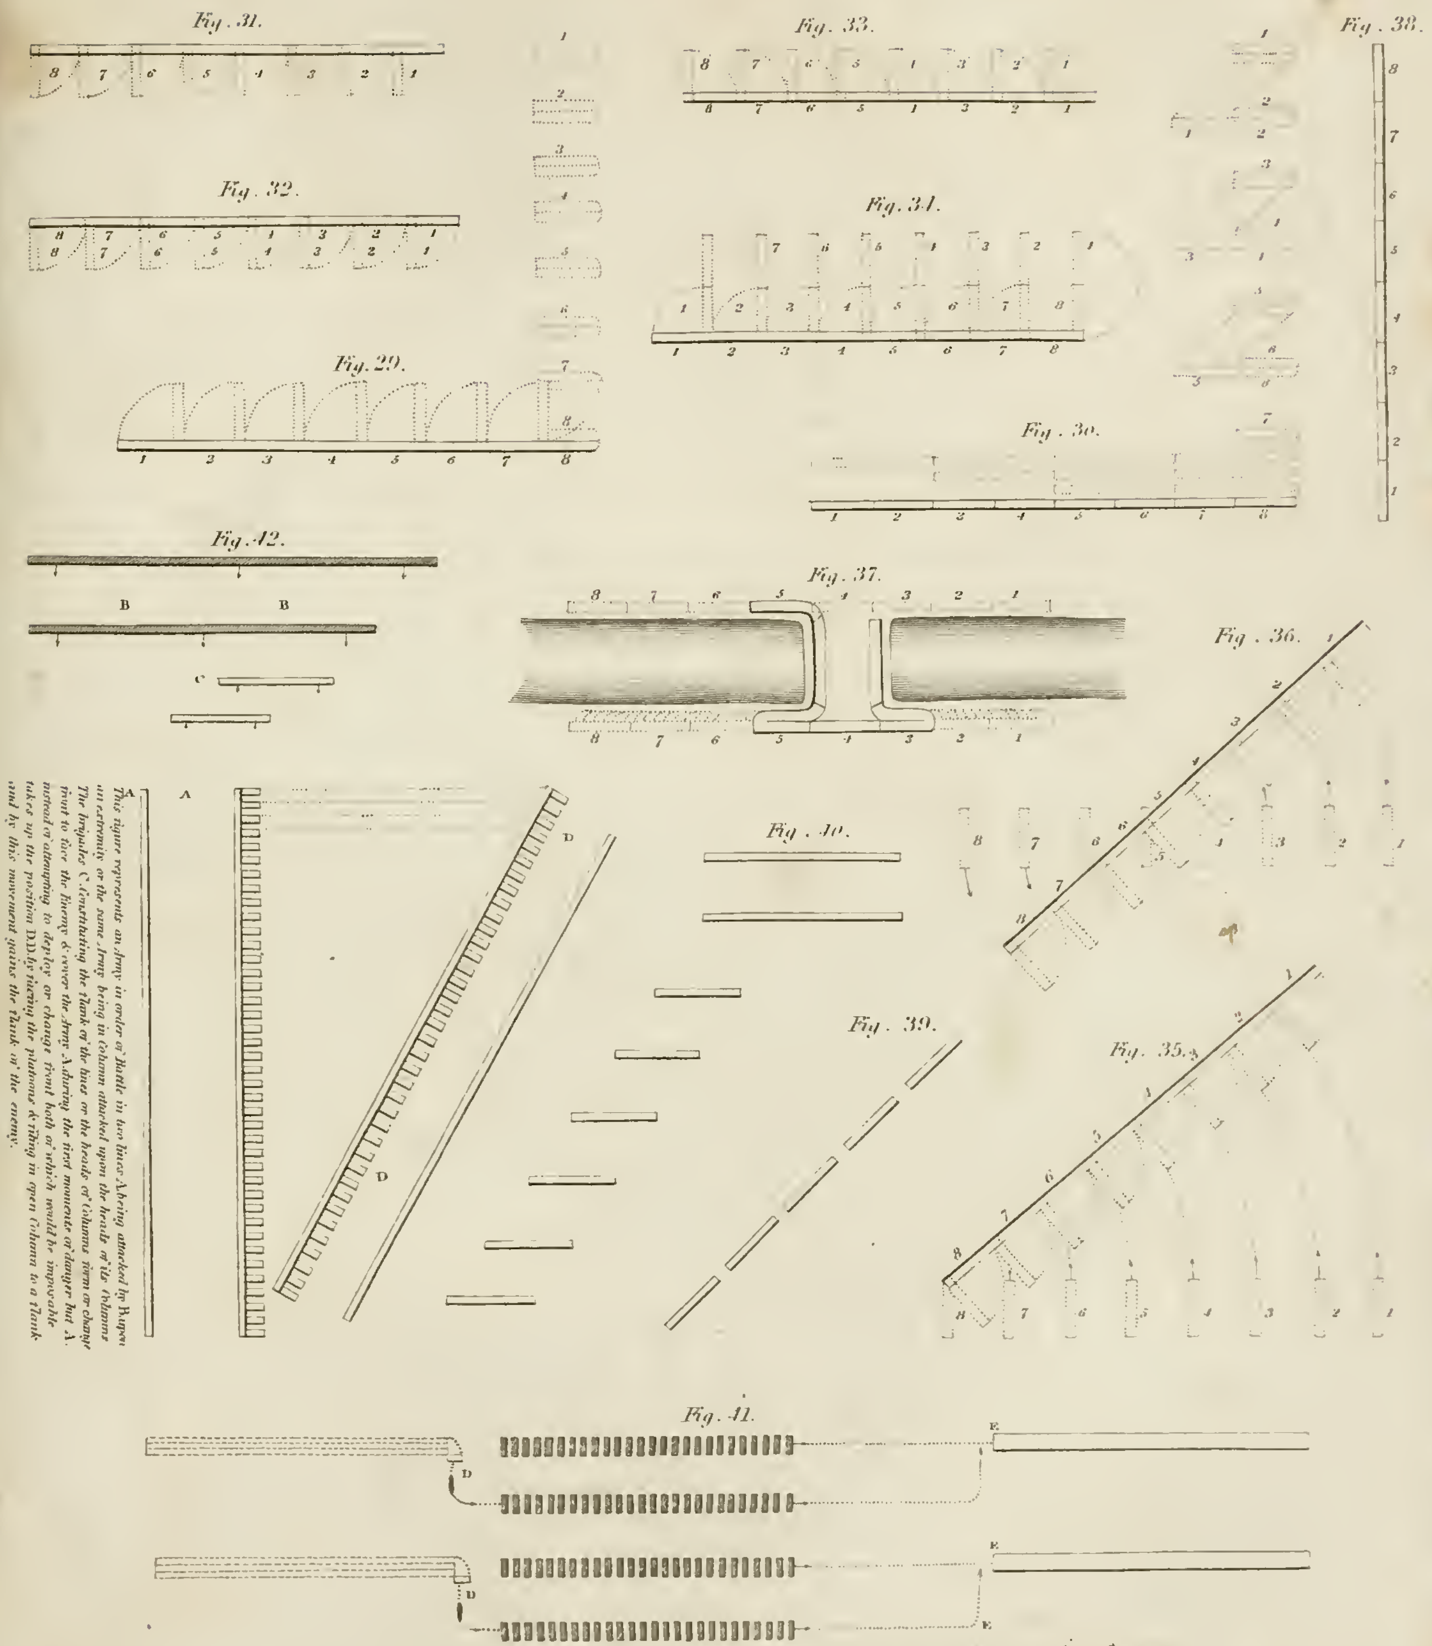
MILITARY TACTICS.

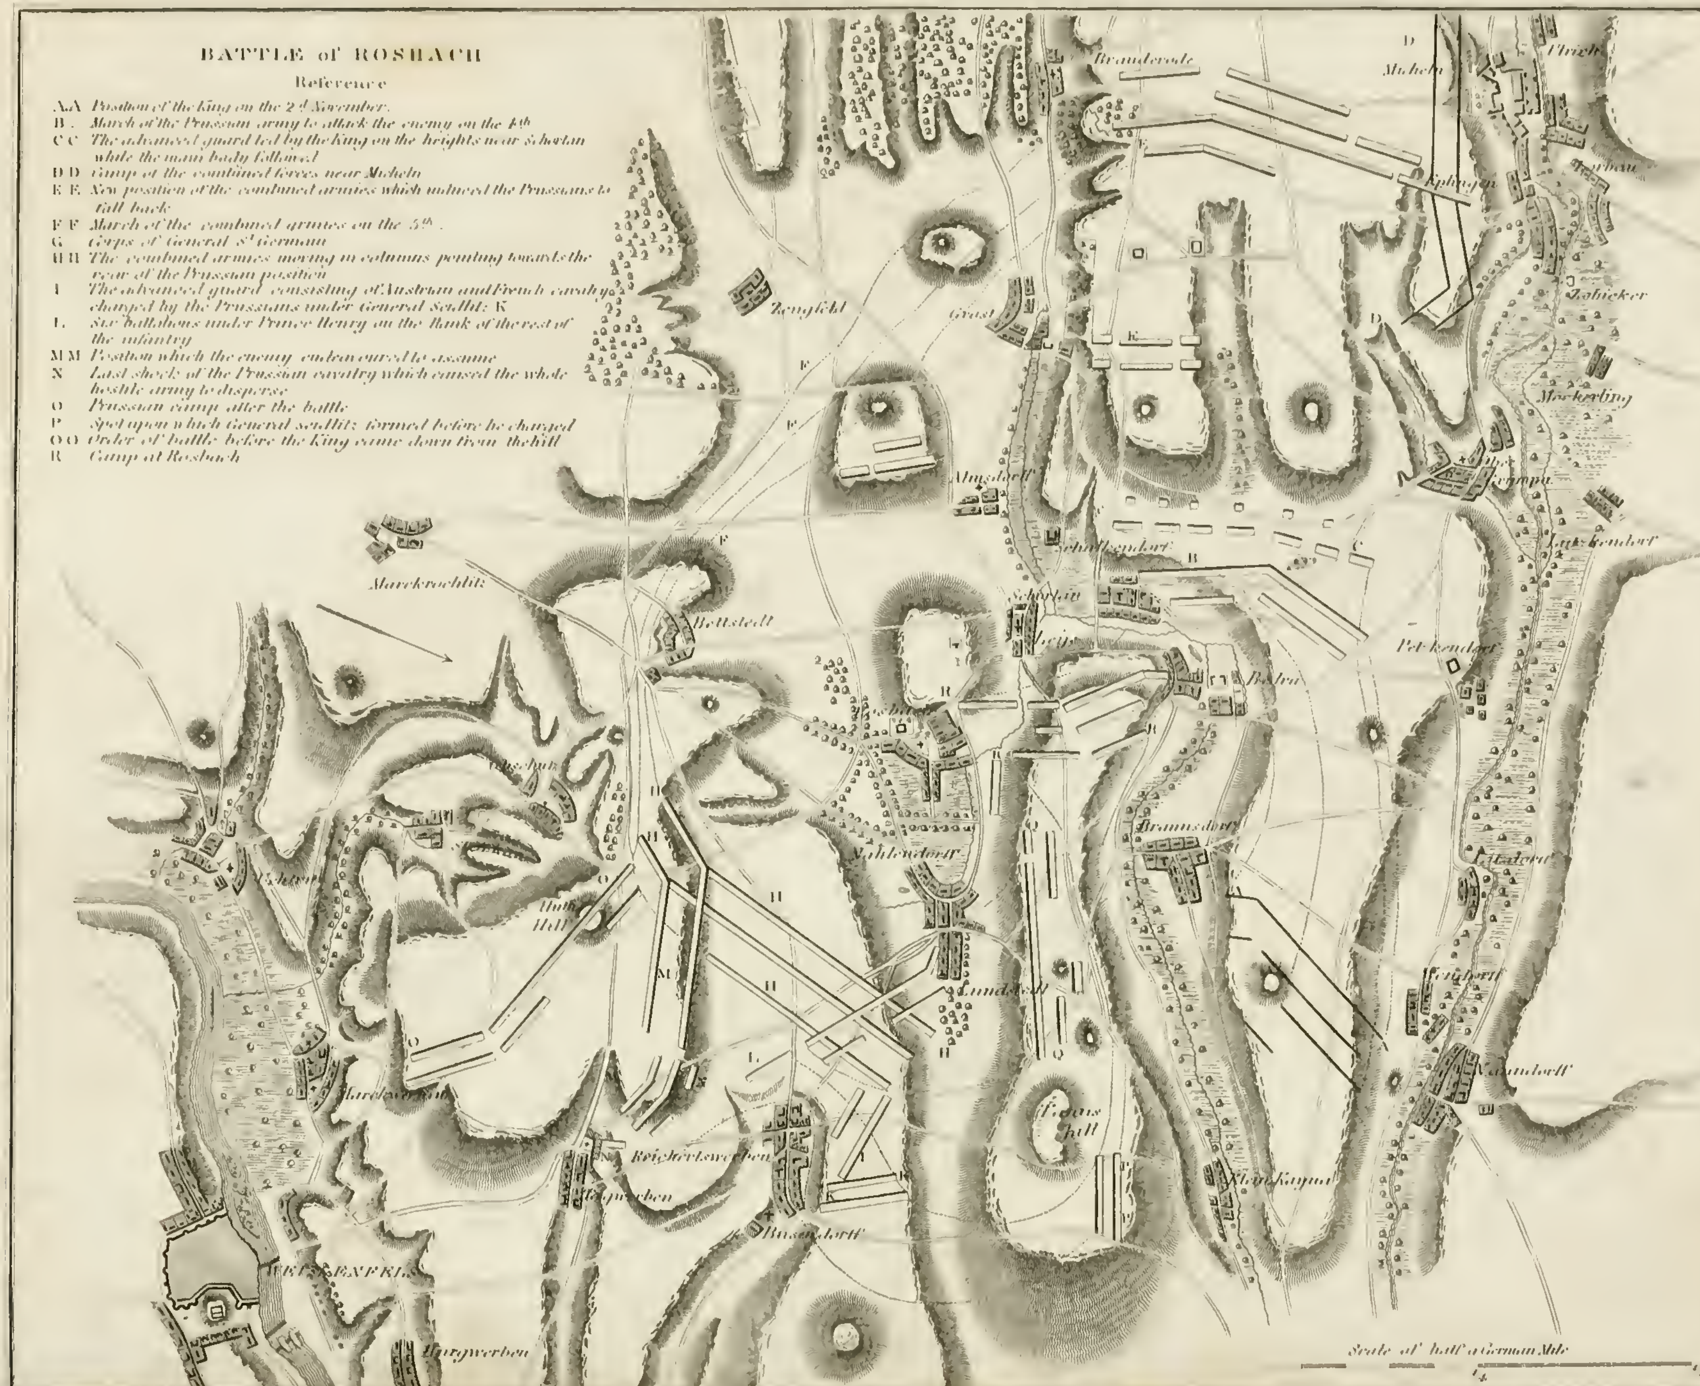
PLATE CCCLXXXI & CCCLXXXII.





Represents an Army marching by lines, doubling the columns in D so as to be in four. the four heads being arrived at E, the 2d and 4th Constituting the left wing halt and allow the others to proceed untill their rear have cleared them when they fall in the line of march & proceed again in two.

Engraved by W Hay.



Engraved by W. Hay.

MILITARY TACTICS. PLATE CCCLXXXVI.

Reference.

- A.A. Austrian grand army in order of battle.
- B. Flank or potence formed by the corps under Nadasti
- C. Advanced corps of Cavalry surprised by the Prussians and driven upon the main body in E.
- D. March of the king in four columns.
- E.F. Point where the four columns formed into two and thence moved in order of battle by the right.
- G. Prussian advanced guard.
- H.I.K. First attacks of the advanced guard sustained by the whole army the enemy giving way H. continued to move forward in column by its left projecting beyond the front of I. by which means it presented a potence the head of which turned the flank and rear of the enemy.
- L.L. The whole line having advanced gradually brought into action
- M. The left wing of the enemy thrown back into the new disposition
- N. General Driesen charging the Austrian cavalry. O.
- P. Right wing of the enemy brought into the new disposition.
- Q. Prussian cavalry of the left wing charging the enemy in flank.
- R. Last position of the Austrians.
- S.S. Again attacked by the whole army of the Prussians.
- T.T. Retreat across the Weistritz by the bridges at Rathen and Lissa and by the pontoon bridges .V.
- V.V. Prussian camp after the battle.

ORDER of MARCH and MANŒUVRES at the BATTLE of KOLLIN

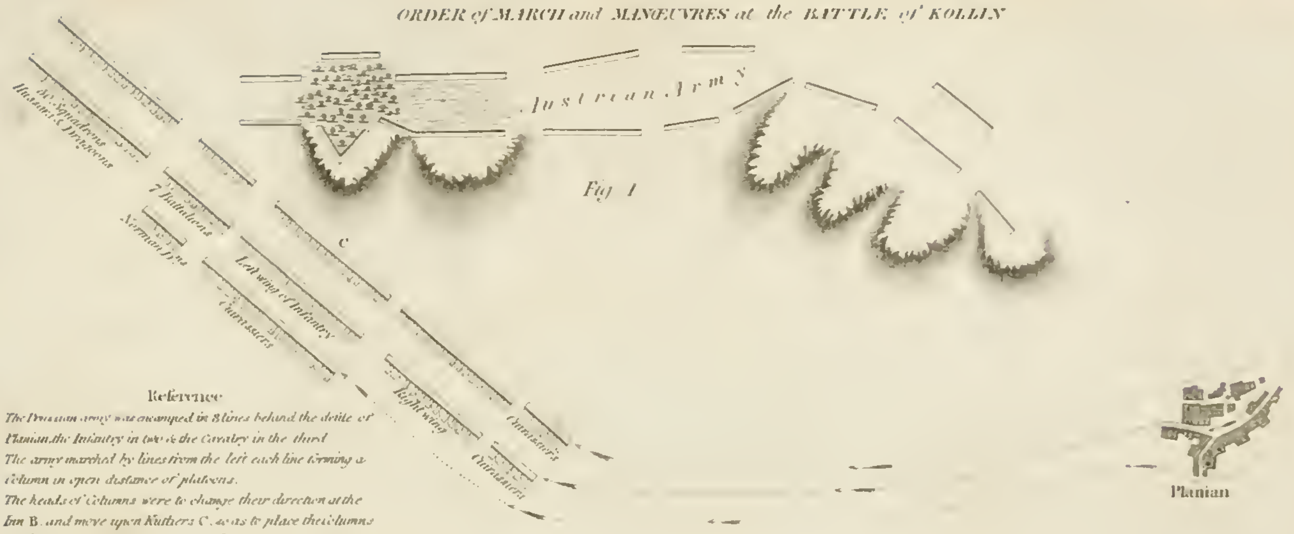


Fig. 1

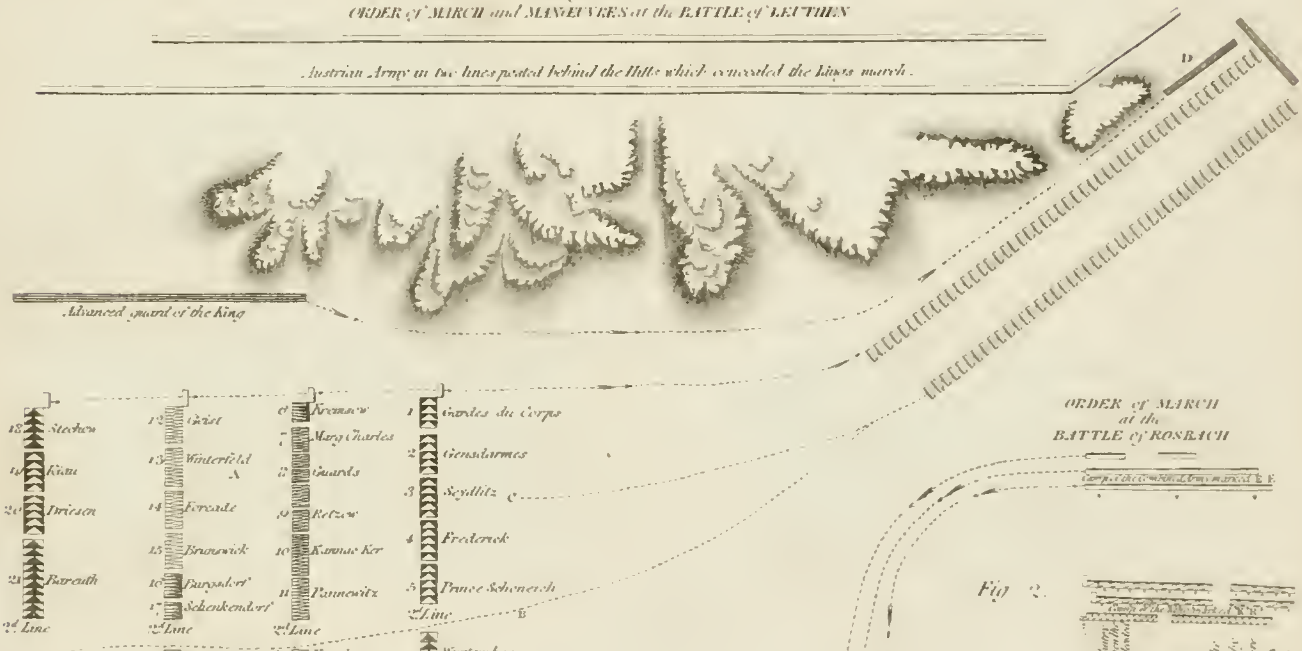
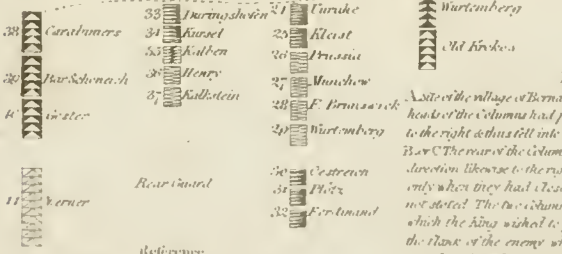
Reference

The Prussian army was encamped in 3 lines behind the defile of Planian the Infantry in two & the Cavalry in the third. The army marched by lines from the left each line forming a column in open distance of platoons. The heads of Columns were to change their direction at the Inn B. and move upon Kuthers C. so as to place the Columns on the line of the order of Battle which was to be effected by wheeling into line and not by deploying.

Fig. 3

ORDER of MARCH and MANŒUVRES at the BATTLE of LEUTHEN





Reference

Infantry	Grenadiers	Lt Infantry
Cuirassiers	Dragoons	Hussars

Reference

A site of the village of Borna between the 2d and 3d Columns when the heads of the Columns had passed it, they changed their direction to the right & thus fell into two Columns ready to wheel into line B & C The rear of the Columns constituting the 2d line changed their direction likewise to the right but whether at the same time as A or only when they had closed up to their proper distance in C. is not stated. The two Columns continued marching in the alignment which the King wished to give his Army, until they had gained the flank of the enemy when they wheeled up and the army stood in order of Battle D. Advanced guard forming an Angle or potence for the first attack B. and C. have both been dotted to denote that possibly the 2d line did not turn until it had reached the point C.

ORDER of MARCH at the BATTLE of ROSBACH

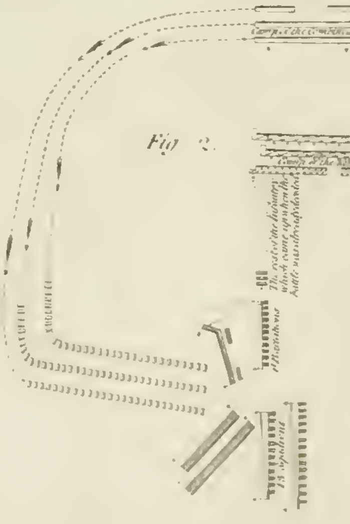


Fig. 2

Reference

The Prussian Army marched by lines from the left the Infantry in platoons and the Cavalry in sections by moving upon the intended alignment the Columns were formed in order of Battle by wheeling up without any deployment the march was concealed by the heights
